Abstract

Worldwide, a relevant surface of arable lands is facing salt stress, and this surface is increasing continuously due to both natural and anthropogenic activities. Nitric oxide (NO) is a small, gaseous molecule with a plethora of physiological roles in plants. In addition to its normal physiological functions, NO protects plants subjected to different environmental cues including salinity. For example, NO mediates photosynthesis and stomatal conductance, stimulates the activity of Na⁺/H⁺ antiport in tonoplast, promotes the biosynthesis of osmolytes, and counteracts overaccumulation of reactive oxygen species in plant cells under salt stress. Exogenous NO is also beneficial for plants subjected to salinity, in which it increases salinity tolerance *via* growth promotion, reversing oxidative damage, and maintaining ion homeostasis. This review provides a comprehensive picture of the NO-mediated mechanisms in plants, resulting in salinity tolerance with a particular focus on the photosynthetic processes, the antioxidant patterns as well as the cross-talk with other regulatory compounds in plant cells.

Additional key words: abiotic stresses, antioxidant systems, osmolytes, photosynthesis, stomatal conductance.

Introduction

The increasing trend of population growth paralleled, unfortunately, the rate of water and soil salinization, posing serious concerns in a near future for the World's food production. Good quality water and soil is the prerequisite for a high yield of the plants. Conversely, one of the most deleterious phenomena, in particular in arid and semi-arid areas, is salinization of water and soils (Rui and Ricardo 2017). During the last century a huge number of aquifers and river basins have become unsuitable for human consumption owing to high salinity. Moreover, every year a large fraction of agricultural land is salinized and becomes unusable (Vengosh 2003). So, in order to enhance crop yield, it becomes necessary to find new strategies for better plant performance in saline conditions

(Hanin *et al.* 2016).

Nitric oxide (NO) is a redox-signaling molecule involved in many physiological processes in plants, and plays key roles in response to challenging growth conditions, including salinity (Zhao *et al.* 2004, Zhang *et al.* 2006b). In particular, it has been demonstrated that NO can enhance salt tolerance through increasing activities of proton-pump and Na⁺/H⁺ antiport in the tonoplast (Zhang *et al.* 2006b). In addition, NO is itself a reactive species and can be either protective or toxic depending to several factors including concentration, the plant species, and the plant developmental stages (Zhao *et al.* 2007). Nitric oxide may therefore act as a chain breaker to minimize the oxidative damage attributable to salt-triggered oxidative stress (Zhao *et al.* 2007, Gadelha *et al.* 2017). This signaling molecule also interacts with other

radicals, antioxidant compounds, and phytohormones taking part to an orchestrated cross-talk between NO and other molecules against salinity (Hasanuzzaman *et al.* 2018). For example, NO mitigates salt stress by regulating amount of osmolytes and antioxidant enzymes in chickpea plants (Ahmad *et al.* 2016). All these aspects suggest that NO is a key metabolite in plant physiology and a depth knowledge of the mechanisms underpinning NO involvement against salinity are of crucial importance to promote the cultivation of plants in marginal area prone to salinity. The present literature survey aims at summarizing the main findings about the physiological roles of NO in plants suffering of salt stress with the scope to provide a comprehensive picture related to the role of this gaseous molecule under salinity, which could be useful for future research on the topic.

Salt stress and its impacts on plants

Salt stress is one of the most predominating abiotic stresses which lead to drastic loss in agriculture in terms of crop yield, majorly in dry and semi dry areas. Hence it is required to understand the various strategies which help in combating salinity stress and developing salt resistant plant cultivars (Tanveer *et al.* 2018). Deposition of excessive concentrations of salts leads to development of initial stress symptoms in the roots: osmotic stress. In the cytosol, long exposure of salt stress causes imbalance of minerals and nutrients. Salt stress consequently leads to oxidative burst due to the generation of reactive oxygen species (ROS) (Acosta-Motos *et al.* 2017, Li *et al.* 2018, Rattan *et al.* 2020). Additionally, uptake and accumulation of excessive salt ions interference with many intracellular metabolic processes. High salt concentration in the soil causes osmotic imbalance which limits water uptake from soil (Munns 2002). High concentration of Na⁺ inhibits the absorption of some nutrient elements. Meanwhile, ionic and osmotic stress will also lead to an imbalance in plant metabolism and above mentioned oxidative stress (Chinnusamy *et al.* 2006). The salt stress decrease the production capacity due retardation in growth and finally can cause the death of the plant. Salt stress adversely disturbs virtually all facets of biological processes, including photosynthesis, protein synthesis, and other primary metabolism pathways (Chartzoulakis and Klapaki 2000, Tanveer *et al.* 2018, Rattan *et al.* 2020). Additionally, under high salt, the most immediate response is the decrease in the cell expansion (Wang and Nii 2000). Parida and Das (2005) showed that salinity disturbs plant photosynthesis by negatively affecting carbon assimilation efficiency. Thylakoid structure of chloroplasts also gets disrupted under salt stress accompanied by reduction in the starch content (Hernández *et al.* 2002). The chloroplasts were found to be aggregated together in the leaves of salt treated tomato. Moreover, no or very low grana and thylakoid structures were observed in chloroplasts (Khavari-Nejad and Mostofi 1998).

Physiological roles of NO in plants

Nitric oxide stimulates development of plants by regulating various growth parameters of primary root, hypocotyl, mesocotyl, adventitious and lateral roots, leaves, and the stem (Neil *et al.* 2008). For example, at low concentrations of NO donor nitroprusside, an acceleration of growth was noted for *Arabidopsis thaliana* primary root, whereas inhibition of growth was observed at higher concentrations (Yemets *et al.* 2009). It is established that NO participates in differentiation of *Zinnia elegans* xylem by regulating cell lignification and the programmed cell death (Ferrer and Ros Barceló 1999). In case of pathogen attack, NO also regulates plant defense system by modulating programmed cell death (Mur *et al.* 2005).

It is suggested that plants with elevated production of NO enter the flowering stage somewhat later than plants with physiologically normal NO content (He *et al.* 2004). Germinating and even non-germinating pollen grains produce NO and nitrate required for the reproduction process. The NO generation is possibly an important component of the signaling system activated by pollen-stigma interaction. Nitric oxide regulates the direction of pollen tube growth, which is very important for fertilization. It was found that interaction of NO produced by the pollen with ROS generated by the pistil stigma can initiate pollination through the onset of signaling cascades between pollen grains and stigmas (Bright *et al.* 2009). In mutant *Arabidopsis* plants (*Atnos1*) with defective NO synthase, reduction in NO biosynthesis was observed accompanied by declined plant growth and stomatal movement. However, overexpression of *AtNOS1* resulted in recovery of plant growth due to NO mediated regulation of plant biology (Guo *et al.* 2003), suggesting roles of this gaseous molecule in plant growth and development. In addition to normal physiological functions, NO regulates plant growth and development under abiotic stresses (Fancy *et al.* 2017, Sharma *et al.* 2020).

Nitric oxide and its physiological roles in plants under salt stress

Nitric oxide plays key roles in mitigating harmful effects of salinity in plants by regulating key physiological processes like photosynthesis, antioxidative defense system and ion homeostasis. The detailed description about NO mediated regulation of plant biology under salt stress is discussed in following sub-sections. The roles of NO in plants under salt stress are summarized in Table 1.

Regulation of photosynthesis: Salt stress severely impact the photosynthetic processes by decreasing chloroplast activity, and hampering photosynthetic rate (P_N), and stomata conductance (g_s) (Teixeira and Pereira 2007, Chaves *et al.* 2009, Guidi *et al.* 2017, Papadakis *et al.* 2019, Sharma *et al.* 2019, Landi *et al.* 2020). Often, stomata limitations to photosynthesis represent the first effect of the osmotic stress promoted by Na⁺ and Cl⁻

Table 1. Nitric oxide induced changes in plant biology during salinity stress in various plants.

Effect of nitric oxide on plant biology	Plant species	Reference
Enhanced activity of tonoplast H ⁺ -ATPase and Na ⁺ /H ⁺ antiporter gene	<i>Zea mays</i>	(Zhang <i>et al.</i> 2006b)
Stimulated root elongation and germination rate	<i>Lupinus luteus</i>	(Kopyra and Gwóźdz 2003)
Increased in viability of leaf, enhancement in productivity	<i>Oryza sativa</i>	(Uchida <i>et al.</i> 2002)
Enhancement in cytosolic K ⁺ content	<i>Triticum aestivum</i>	(Ruan <i>et al.</i> 2004)
Enhancement in proline synthesis	<i>Lycopersicon esculentum</i>	(Wu <i>et al.</i> 2011)
Enhanced accumulation of polyamines like spermidine	<i>Cucumis sativus</i>	(Fan <i>et al.</i> 2013)
Enhanced activity of antioxidative enzymes and content of proline; reduction in malondialdehyde content	<i>Brassica juncea</i>	(Zeng <i>et al.</i> 2011)
Decreased Na ⁺ content with simultaneous increase in K ⁺ content	<i>Kosteletzkya virginica</i>	(Guo <i>et al.</i> 2009)

accumulation in plant tissues (Chaves *et al.* 2009, Sotiras *et al.* 2019). In a second phase, when both ions accumulate at toxic level, photosynthesis can be further reduced by damages to chloroplast, and in particular to photosystem II (Pompeiano *et al.* 2017).

Nitric oxide has been demonstrated to revert the adverse effect of salinity to the photosynthetic machinery in many instances. For example, gas exchange and chlorophyll fluorescence parameters were found to be less impaired in *Hordeum vulgare* and *Lycopersicon esculentum* seedlings under saline conditions when treated with exogenous NO (Zhang *et al.* 2006a, Wu *et al.* 2011). Amelioration of photosynthesis was observed in plants subjected to salinity by the application of NO with or without sulfur (S) (Fatma *et al.* 2016a). However, maximal increase in photosynthesis was noted with the combined treatment of NO plus S. Nitric oxide independently or in combination with S promoted the synthesis of glutathione, assimilation of S, optimum production of NO and redox state, which represent the bases of NO-triggered defensive mechanism of mustard plants (Fatma *et al.* 2016b). Recent reports suggest that NO treatment reduced the salt toxicity by enhancing the efficiency of photosynthetic system in mustard plants (Jahan *et al.* 2020). It has also been demonstrated that application of NO increased photosynthesis through increase of Rubisco activity and g_s (Fatma and Khan 2014). Nitric oxide induce the expression of the plasma membrane H⁺-ATPase required for a balanced K⁺:Na⁺ ion ratio providing protection against salt stress (Zhao *et al.* 2004). Indeed, the maintenance of a balanced K⁺ flux is essential to control stomata aperture under salinity. The exogenous application of NO in plants of *Triticum aestivum* induced stomatal opening that were partially reversed by salt stress (Sehar *et al.* 2019). In NO-treated plants, the lower impact on stomata closure resulted in a lower decline of P_N when plants were subjected to salinity. The authors hypothesized that application of NO increased GSH content which played a role in cellular redox homeostasis and regulation of stomatal movement. GSH has also been reported to interact with ABA to regulate stomata movements (Misra *et al.* 2015).

NO responses also correlated with the amount of nutrients available to the plant. According to Wang *et al.* (2013) the improvement of the process of photosynthesis,

biosynthesis of chlorophylls, and transpiration rate depended upon the availability of Mg and Fe in perennial ryegrass. Apart from this, exogenous treatment of NO along with salicylic acid also stimulated the uptake and translocation of Fe in *Arachis hypogaea*, even in the presence of salt stress (Kong *et al.* 2014), which could be a remarkable factor for salt-stress tolerance. The mechanisms involved in regulation of photosynthesis by NO under salt stress are shown in Fig. 1.

Regulation of reactive oxygen species and enzymatic antioxidants: Against oxidative stress, NO plays a crucial role in resisting the stress (Ahmad *et al.* 2016, Sharma *et al.* 2020). Salt stress causes changes in the assimilation pathway of nitrates and sulphates by altering the expression of various enzymes, further depressing their energy status, and enhancing nitrogen and sulfur demands. Injuries caused at cellular level are mainly due to the oxidative damage generated by ROS produced in saline conditions.

Various detoxification strategies are developed by plants growing under salinity, such as boosting up the activities of certain antioxidative enzymes like superoxide dismutase (SOD), guaiacol peroxidase (POD), catalase (CAT), ascorbate peroxidase (APOX), glutathione reductase (GR) along with certain non-enzymatic antioxidants like tocopherols, glutathiones, ascorbates which help in scavenging of free radicals (Nazar *et al.* 2015). Nitric oxide helps in regulation of salt induced oxidative stress and increasing resistance of plants growing in those challenging conditions. For example, when NO is applied to maize plants, reduction in the content of hydrogen peroxide was observed, accompanied by the activation of antioxidative defense system of maize that led to amelioration of free radical content and improvement in cell viability (Farooq *et al.* 2009). Oxidative damage caused by salt stress in *Brassica juncea* plants were significantly overcome by the exogenous NO which further stimulated the activities POD, SOD, APX, and GR (Zeng *et al.* 2011). In *Oryza sativa*, NO treatment significantly alleviated salt stress by modulating expression of antioxidative enzymes resulting in enhanced salt resistance (Uchida *et al.* 2002). The overview of mechanisms involved in regulation of oxidative stress by NO is given in Fig. 2.

Regulation of other metabolites: Biosynthesis of proline enhances in the cytosols with the treatment of NO. For example, in *Kosteletzkya virginica* plants accumulation of proline in cytosol was drastically stimulated under salt stress when SNP was applied (Guo *et al.* 2009). Similarly in wheat plants, free radicals were efficiently scavenged and stabilization of macromolecules occurs with enhancing the content of proline after NO treatment under salinity (Ruan *et al.* 2002). Additionally, NO promote accumulation of proline in coordination with sugars. For example, in *Lycopersicon esculentum*, application of NO resulted in enhanced proline and sugar content leading to increase in salt tolerance (Wu *et al.* 2011). In tomato plants retardation in the content of photosynthetic pigments were

reported due to salt stress, but enhanced content of proline after NO treatment significantly ameliorated the negative impacts of salinity (Wu *et al.* 2010). Regulation of proline accumulation by NO under salt stress is directly related to the reduction of harmful ROS and better salt tolerance in plants (Guo *et al.* 2009).

Glycine-betaine (GB) plays crucial role in regulation of salt stress in plants. Nitric oxide also helps in regulating the GB mediated stress responses in salt stressed plants (Kumari *et al.* 2019). Further, these researchers observed that transcription and activity of betaine aldehyde dehydrogenase (BADH) in light-grown seedling cotyledons were found to be very high in comparison to those seedlings which were grown in dark when facing

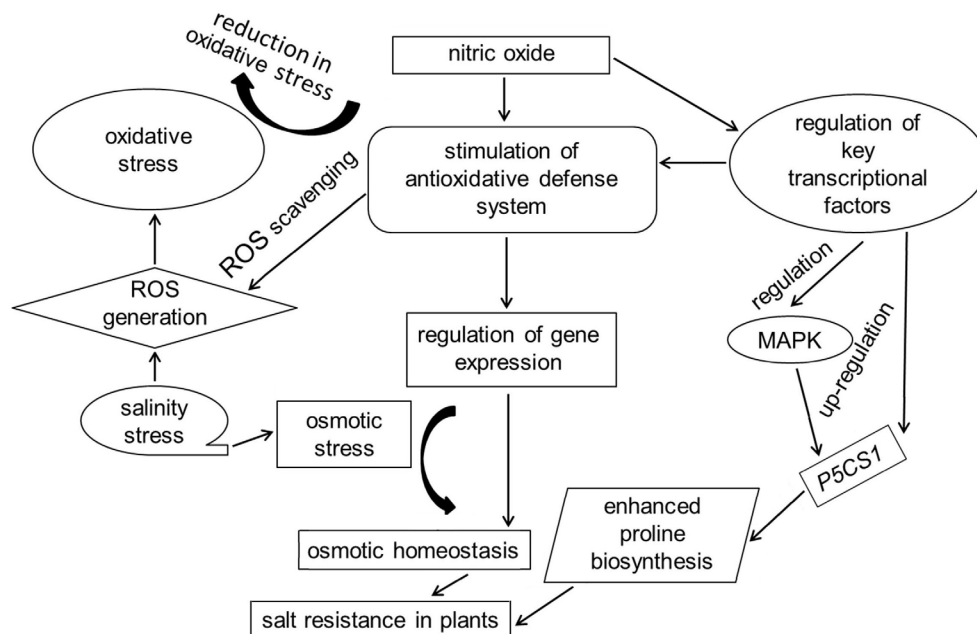

Fig. 2. A mechanism showing the alleviation of salt stress in plants by exogenous application of nitric oxide. P5CS1 - pyrroline-5-carboxylate synthetase, MAPK - mitogen-activated protein kinase, ROS - reactive oxygen species.

the salinity stress. Application of diethylenetriamine, a NO donor also contributed in maintaining the activity of BADH, hence maintaining the homeostasis of GB. It suggests a possible crosstalk between NO and GB in counterattacking the salinity stress (Kumari *et al.* 2019). This modification in the GB content occurs after application of NO due to BADH transcriptional regulation or nitrosylation. Additionally, NO has potential to stimulate the synthesis of osmolytes under salinity stress (Ruan *et al.* 2004) and can also establish a relation between salt stress, NO application/deposition and stimulation of osmolytes like proline which further boost quenching of free radicals.

Polyamines are also involved in salt stress tolerance and their regulation by NO further improves the salinity resistance of plants. For example, in cucumber seedlings, application of SNP triggered the biosynthesis and accumulation of polyamines (Fan *et al.* 2013). These researchers noticed that in comparison to control plants, content of spermine, spermidine, and putrescine decrease in the salt stressed plants in dose-dependent manner. Additionally, in presence of NO, activity of polyamine oxidase was also improved accompanied by enhancing resistance to salt stress (Fan *et al.* 2013).

The role of NO in regulating leaf water content is dependent upon abscisic acid (ABA) at low concentrations of salts, whereas at high concentrations, maintenance of leaf water is done by NO mediated closing the stomatal aperture (Hua *et al.* 2004). For the regulation of stomatal oscillations, ABA signaling is facilitated by NO in guard cells. With reduction of the NO content, stomatal closure induced by ABA is retarded (Steven *et al.* 2002). The transpiration rate is retarded in various plants like *Salpichroa organifolia* and *Vicia faba* by the application of NO, which further causes closing stomata *via* ABA modulated pathways (García-Mata *et al.* 2001). However, when inhibitors of NO were supplied, it reverse NO-induced stomatal closure (Bright 2006).

Regulation of ions by nitric oxide under salt stress

As mentioned above, NO also regulates the ion balance in plants resulting in better salt stress tolerance. In *Zea mays* NO application resulted in improvement of the salt resistance by enhancing the Na⁺/H⁺ antiport along with proton-pump activity of the tonoplast (Zhang *et al.* 2006b). In sunflower seedlings, NO modulated the biochemical responses under salt stress by regulating the ratio of Na⁺/K⁺ ions accompanied by better salt tolerance (David *et al.* 2010). Nitric oxide also regulates ions like K⁺, Mg²⁺, Ca²⁺ in plants facing salt stress. This NO mediated ion regulation is further accompanied by a reduction in oxidative stress and improvement of plant growth in terms of better photosynthetic rate, chlorophyll content, stomatal conductance, transpiration rate, and enhanced activities of antioxidative enzymes (Khoshbakht *et al.* 2018).

Conclusions and future perspectives

Though several NO-mediated mechanisms have been described in plants subjected to salt stress, and most of them are able to ameliorate plant growth and reproduction. Among others, NO reacts and interacts with other signaling compounds, describing a finely-tuned and well-orchestrated network once plants experience saline conditions. In addition, it contributes in regulating H⁺-ATPase thereby balancing Na⁺/K⁺ ratio under salinity and promoting the biosynthesis of some osmolytes, which can be useful to prevent salt-triggered water stress. Nitric oxide also interacts with ROS, and has been shown to regulate salt stress responses and programmed cell death. It is conceivable that many other key aspects about this versatile compound are yet to be described.

Further researches are necessary to deepen the signaling behavior of NO in signal transduction in addition to transcriptional regulation and ion detoxification. The advancement of research focusing on NO might be helpful in understanding the involvement of this compound in plants under stress, thereby posing the bases to use NO as a possible strategy to improve salt tolerance and valorize marginal (salinized) lands. This might be helpful to both counteract soil erosion and increase the productivity of these marginal areas, in the attempt to contribute in food supply to a raising human population.
