CONTRIBUTION TO THE VASCULAR FLORA OF PAPASIDERO (NORTH-WESTERN CALABRIA, ITALY)

Abstract - A floristic survey of the Papisidero municipality (54.65 km²) was carried out from 2008 to 2011, allowing us to list 580 specific and infraspecific taxa (567 verified by us), belonging to 353 genera and 89 families. Several species are rather interesting from a phytogeographic and/or conservation point of view. 14 exotic species were also recorded, 10 of which are considered invasive in the regional flora. The most represented families are Asteraceae (66 taxa), Fabaceae (56), Lamiaceae (40), Poaceae (31), while most represented genera are *Trifolium* (11), *Euphorbia* and *Ophrys* (9), *Lathyrus* and *Geranium* (8). Biological and chorological spectra show a clear dominance of Hemicriptophytes and Mediterranean elements respectively, as one can expect based on the climatic conditions of the area at issues.

Key words - Biodiversity, flora, floristic richness, Italy, phytogeography, Calabria.

Riassunto - Contributo alla flora vascolare di Papisidero (Calabria nord-occidentale, Italia) - Negli anni tra il 2008 ed il 2011 è stata effettuata una ricerca floristica nell'ambito del territorio comunale di Papisidero (54,65 km²), che ha permesso la redazione di un elenco di 580 taxa specifici e sottospecifici (di cui 567 da noi verificati), appartenenti a 353 generi ed 89 famiglie. Svariate entità sono risultate di interesse fitogeografico e/o conservazionistico. Le specie esotiche identificate ammontano a 14, 10 delle quali sono considerate invasive per la flora regionale. Le famiglie maggiormente rappresentate sono le Asteraceae (66 taxa), Fabaceae (56), Lamiaceae (40), Poaceae (31); mentre i generi maggiormente rappresentati sono *Trifolium* (11 taxa), *Euphorbia* ed *Ophrys* (9), *Lathyrus* e *Geranium* (8). L'analisi degli spettri biologico e corologico mostra, rispettivamente, la prevalenza di Emicriptofite e di elementi Mediterranei, in accordo con le condizioni climatiche che caratterizzano l'area.

Parole chiave - Biodiversità, flora, ricchezza floristica, Italia, fitogeografia, Calabria.

INTRODUCTION

Papisidero municipality (province of Cosenza) represents an area of ecological importance located in the north-western part of Calabria (South Italy) (Fig. 1). It totally falls within the Pollino National Park, and it is partially protected by the natural reserve «Valle del Fiume Lao», instituted in 1987 for the protection of many undisturbed and well preserved landscapes, densely wooded and representing important habitats for some endemic animals. The municipality has as

extent of 54.65 km², ranging from 75 to 1,462 m a.s.l. The highest peak is Mt. Ciagola, while other reliefs does not reach 1,100 m.

Floristic information concerning Papisidero are quite poor. According to Bernardo *et al.* (2005), this area is scarcely known and investigated. Some useful data are available for the near upper part of the Lao river basin, thanks to the surveys carried out by botanist Biagio Longo (Longo, 1893, 1894, 1902).

As concerns Papisidero, there is only one record provided by Longo, that is *Erica multiflora*. Other recently recorded plants have been published between 1990 and 2011 by various authors (Cenci *et al.*, 1990; Bianchini & Di Carlo, 1992; Brullo & Spampinato, 1997; Snogerup & Snogerup, 2001; Peruzzi & Gargano, 2003; Peruzzi & Gargano, 2004; Di Marco & Peruzzi, 2009; Di Marco & Peruzzi, 2010; Di Marco *et al.*, 2010; Di Marco *et al.*, 2011). It is a list of 53 taxa, 36 of which collected near the Lao river.

GEOLOGICAL, GEOMORPHOLOGICAL AND CLIMATIC FEATURES OF THE AREA

The so-called «Monte Ciagola group» belongs to the southern Apennine (Bernardo *et al.*, 2011). It is located near the Montea-Caramolo mountains, situated in the south-western portion of Pollino National Park, comprising mainly limestone and dolomitic-limestone formations. From the geological point of view, the «Monte Ciagola group» is very similar to these mountains, belonging to the same geological unit. In Papisidero municipality in detail crystalline-schist formations and Triassic flint are prevailing (Napolitano & Grisolia, 1991).

The geomorphology of this area is irregular: the landscape is mainly mountainous, with slopes, cliffs and several gorges due to the water erosion on carbonatic rocks. Actually, there are many springs and streams in the area. The Lao river is the main river: although it has a torrential regime, it is characterized by conspicuous mean rate flows and it represent the Calabrian river with the maximum low water rate flow (Napolitano & Grisolia, 1991).

Papisidero has a typical Mediterranean climate, with mild temperatures and heavy rainfall. In average 1470.9 mm of rainfall each year. Most rainy months are December (257 mm) and January (223.4 mm); July is the most dry (18 mm) (www.arpacal.it). The annual mean temperatures, in the Lao basin near Papisidero, is ranging from 12 to 14 °C (www.regione.calabria.it).

MATERIALS & METHODS

Field researches were carried out during the years 2008-2011 in 23 sampling localities (Fig. 2), which were selected in order to include the different habitat typologies, such as pastures, dry grasslands, rocky habitats, garigues, riparian areas, scrubs, woodlands, wet habitats and artificial environments.

For the species identification we mainly used Pignatti (1982), but in many cases we also considered updated monographs (Cenci *et al.*, 1990; Raffaelli, 1991; Brullo *et al.*, 1999; Davis, 1999; Ricceri & Arrigoni, 2000; Sno-

Scientific names are attributed according to Conti *et al.* (2005, 2007) or even most recent works. The family circumscription and systematic order follows Peruzzi (2010). Life forms and chorological types are assigned according to Pignatti (1982). Several species (*Cupressus sempervirens* L., *Pinus halepensis* Mill., *Pinus pinaster* Aiton s.l. and *Juglans regia* L.) are excluded from the biological and chorological analyses, being cultivated or coming from reforested areas. For each taxon all the localities of occurrence (coded as numbers according to Fig. 2) are recorded. Dried specimens (*exsiccata*) are preserved in PI and CLU. The taxa not found by us, but recorded in literature are marked by the symbol «*».

In order to establish the typology of exotic species at regional level (invasive, naturalized, casual), we referred to Celesti-Grappo *et al.* (2010). Finally, we checked Conti *et al.* (1997) to verify the regional conservation status for each taxon, according to the IUCN categories. The floristic richness expected for the area was calculated according to Cristofolini (1998), by means of the extrapolation of a locally valid linear regression formula between the logarithm of considered areas extent (in km²) and the logarithm of the respective taxa densities (n° taxa/km²) (Table 1). For this aim, we considered the subregional Calabrian floras published in the last 40 years (La Valva & Ricciardi, 1978; La Valva, 1984; Maiorca & Spampinato, 1994; Bernardo & Maiorca, 1997; Maiorca *et al.*, 2002; Musarella & Tripodi, 2004; Maiorca *et al.*, 2007; Maiorca & Puntillo, 2009). The regression line represents the expected taxa density logarithm, according to the area extent logarithm. By applying this methodology it is possible to obtain an objective measure of floristic diversity, irrespective of the size of the area.

Tab. 1 - Expected and observed floristic diversity in subregional Calabrian floras published in the last 40 years. The values of observed and expected n° taxa/km² ratio higher than 1 are marked in bold font.

CONCLUSIONS

This survey allowed to verify the occurrence of 567 taxa, to which other 13 taxa, reported by previous authors but not found by us, should be added. Therefore, we have listed 580 specific and infraspecific taxa, belonging to 353 genera and 89 families. The prevailing family is Asteraceae, followed by Fabaceae, Lamiaceae, and Poaceae. These 4 families contain approximately one third of the total taxa. Apiaceae, Orchidaceae, and Brassicaceae are also well represented. The richest genera are *Trifolium* (11 taxa), *Euphorbia* and *Ophrys* (9 taxa), *Lathyrus* and *Geranium* (8 taxa). The observed floristic richness for Papisidero was lower than expected (726 taxa, according to the linear regression formula), with a ratio observed / expected of 0.80, a value that places Papisidero under the regression line (Fig. 3). This result could be explained for the presence of unreachable and not sampled areas or to a low environmental variability, since the area is rich also in uncultivated fields.

The biological spectrum (Fig. 4) shows a dominance of Hemicriptophytes (38.7%), typical of temperate re-

gions, followed by Therophytes (27.6%), typical of cultivated and uncultivated fields. Geophytes, usually spread in pastures and dry grasslands, came third (15.1%). Then there are Phanerophytes and Nanophanerophytes (10.7% altogether), testifying the richness of woodlands, and finally Chamaephytes (7.8%), which are usually prevailing in dry habitat such as garrigues, cliffs or arid slopes.

Also the chorological spectrum (Fig. 5) reflects the climatic and environmental features of the area at issue. In fact, Mediterranean element prevails, in particular the Stenometiterranean (21.2%) followed by Eurimediterranean (20.3%). Species with a wide distribution (Cosmopolitan and Subcosmopolitan) came third (11%), likely favored by the occurrence of sinanthropic and wet habitats. Lastly, Eurasiatic (8.3%) and Palaetempere (7.3%) are following, suggesting the presence of mild climate conditions.

Italian endemic taxa (Table 2) are 29 (5.9%). Most of these endemics are circumscribed to southern and south-central Apennine, or to Sicily-southern Italy.

The endemic taxa with the most narrow distribution are: *Achillea rupestris* subsp. *calcareae*, *Alyssum difusum* subsp. *calabriticum*, *Picris scaberrima* (Basilicata and Calabria) and *Micromeria consentina* (Calabria and Sicily).

The exotic taxa (Table 3) are 14, but 10 of them are considered invasive exotic elements in the regional flora. Then there are 3 casual and 1 naturalized exotic species.

5 species (*Silene catholica*, *Orobanche lavandulacea*, *Plantago sempervirens*, *Carum heldreichii*, *Portulaca nitida*) and one subspecies (*Galanthus reginae-olgae* subsp. *reginae-olgae*) were only recently recorded for the Calabrian flora. Some of these taxa are rather relevant from a phytogeographic and / or conservation point of view: *Carum heldreichii* and *Silene catholica* are Amphidriatic species and *Galanthus reginae-olgae* subsp. *regi-*

nae-olgae is hiterto recorded in Italy for Tuscany, Calabria and Sicily. Moreover, we identified for Papisidero 3 very rare taxa, *Ophrys lacaitae*, *Solenopsis minuta* subsp. *nobilis* and *Athamanta ramosissima*, quite rare for the Calabrian and Italian flora. The taxa included in regional (Conti *et al.*, 1997) and/or national (Scoppola & Spampinato, 2005) red lists are 26 (Table 4).
