Abstract Thirty-five adult waterfowl (14 males and 21 females) representing varies the hunting season from 2015 to 2016. Antibodies to Neospora caninum while heart and brain were subjected to molecular analysis for the detect (34.3%) (6 Anas crecca, 3 Anas platyrhynchos, 2 Anas penelope, 1 Ana caninum, while 10 animals out of 35 (4 Anas crecca, 2 Anas platyrhynchos) vanellus vanellus) scored positive for at least 1 sample, with an overall for the first time the occurrence of antibodies and N. caninum DNA in we present report, which feed directly from the soil and/or water, would be a hosts and could contribute to parasite transmission in the sylvatic cycles these avian species in the epidemiology of this protozoan, the presence bioassay and/or culture, as well as histological evidence of N. caninum	n were detected by IFAT on blood samples, ction of Neospora caninum DNA. Twelve birds as acuta) showed antibodies versus N. hos, 2 Anas penelope, 1 Anas acuta, and 1 prevalence of 28.6%. The present report shows aterfowl. The avian species investigated in the able to ingest oocysts excreted by final canid. To achieve a definitive result about the role of e of viable parasites should be demonstrated by
