Title: Evolution of the Anisakis risk management in the European and Italian context

Article Type: Review Article

Keywords: Anisakids, risk management, European legislation, raw fish products.

Abstract: Due to the social and legislative implications, the presence of Anisakis spp. larvae in fishery products has become a concern for both the consumers and the official Control Authorities. The issuance of a large number of provisions, aimed at better managing fish products intended to be consumed raw or almost raw and the associated risks, resulted in a very complicated legal framework. In this work, we analyzed the evolution of the normative through an overview on the local and international legislation, focusing on issues that are of practical interest for Food Business Operators (FBOs) in the fishery chain. In addition, we performed a survey across the Departments of Prevention of the Italian Local Health Authorities (LHA) and the main fish markets in Italy to collect the operating procedures and the monitoring plans. Overall, we found many differences, due to the absence of a national reference standard for the management of the Anisakis risk. From this examination, it turns clear that only a participation of all the involved Institutions, a strategy of synergistic interventions, as well as a correct training of FBOs, can result in an effective risk management and a proper risk communication, which should overcome states of confusion and unnecessary negative impacts on the economy.
Dear Editor,

We would like to submit the following manuscript for possible publication:

“Evolution of the Anisakis risk management in the European and Italian context”

The Anisakis risk management has recently been a source of great concern worldwide for both consumers and the Official Authorities in charge for controls. At the international levels, authorities, such as the Codex Alimentarius Commission, the EFSA and the U.S. FDA have recognized the need to face this issue through the adoption of preventive measures, capable to reduce, or even eliminate, the risk for public health.

The increased perception of this risk has determined, over the years, the issuance of a large number of international provisions, which have created a legal framework aimed at better managing fish products intended to be consumed raw or almost raw and its associated risks.

In this manuscript we revisited the evolution of the legislation related to the Anisakis risk, with an excursus of all European and Italian amendments issued from the late 60s to date. In particular, we addressed those aspects that, in our opinion, need to be reconsidered. Moreover, thanks to the collaboration of an Official Veterinary who has been working for more than 30 years at the wholesale market of Milan, we took into consideration many practical issues that are of interest for people working in the fishery chain.

Our aim was not only to provide an update on this topic, but to also analyze the data obtained from a survey of operating procedures and the self-monitoring plans, gathered at the Department of Prevention of the Italian Regional Health Authorities (AZ. USL) and at the main fish markets.

Other than to the academic world, this work is addressed to all those, who daily deal with the management of the fishery products as Food Business Operators (manufacturers, vendors, caterers), responsible for self-monitoring plans, and Official Authorities, to better clarify the tasks that they are called to fulfill.

Best regards,

Andrea Armani
Dear Editor,

we revised the manuscript according to the suggestions of the Reviewers. Our answers, comments and rebuttals are listed below. The modified parts have been written in green to facilitate the revision process.

Reviewer #1: Manuscript Number: FOODRES-D-14-01201
Title: Evolution of the Anisakis risk management in the European and Italian context

This work carries out an overview on the legislation about Anisakids which are the most important fish parasites from a sanitary point of view. The content is of interest; however, some important deficiencies are included:

(AZ. USL) The authors have to explain its meaning.

Az. USL is the acronym of Azienda Unità Sanitaria Locale. Its name, in English, is Local Health Authority (the name in the text has been modified from Regional Health Authorities to Local Health Authorities). Az. USL has been removed from the text to avoid confusion.

The authors affirm: "In fact, hypersensitivity reactions may also occur either via or with cooked fish, since allergens are thermostable". There are not evidences about this possibility. Nowadays, we can accept that allergic reactions only occur when live larva are ingested in raw or undercooked parasitized fish.

The sentence has been modified and, according to the suggestions of reviewer N.3, a short paragraph on the ongoing debate on the necessity of larvae being alive to induce allergy the first time has been added (line 134-154)

Anisakiasis should be changed by anisakiosis. According to the following paper: T. KASSAI, M. CORDERO DEL CAMPILLO, J. EUZEBY, S. GAAFAR, Th. HIEPE and C.A. HIMONAS Standardized Nomenclature of Animal Parasitic Diseases (SNOAPAD) Veterinary Parasitology, 29 (1988) 299-326 299, "the disease name is constructed solely by the suffix -osis, which is added to the stem of the name of the parasite taxon, formed from the nominative of the taxa". Besides, the reference of Audicana and Kennedy 2008 should be changed by Kassai et al 1988.

Anisakiasis has been changed in anisakiosis and Kassai et al 1988 (line 128) has been added in the text.

Hysterothylacium belongs to the family Anisakidae, but to the subfamily Raphidascaridinae Hartwich, 1954. Please include this in the text.

In this work we used the classification of Fagerholm, 1991, due to the fact that molecular analyses performed to investigate phylogenetic relationships in the superfamily Ascaridoidea support this classification (Murrell, K. Darwin, and Bernard Fried. Food-borne parasitic zoonoses: fish and plant-borne parasites. Vol. 11. Springer, 2007 report two different accepted classification for ascaridoid). For further explanations see answers to the Reviewer 2. Moreover, a new paragraph has been added in the manuscript (line 82-89).

Infestation should be changed by infection.

Infestation has been changed in infection in all the manuscript.

**The sentence has been modified and the reference has been removed (line 173-176)**

**Reviewer #2**: The topic of this review is interesting. However, in my opinion there is too much generic information. Although this review does not present any new knowledge, after some revisions, it could give contribution in this field.

Detailed reviewer comments:

**ABSTRACT**

The abstract is not sufficiently informative and the objective is not clear (line 35…we analyze the data obtained etc…)  

**The abstract has been changed according to the suggestion**

Line 34: operator working in….it could be replaced with food business operators in…  

**Done (line 34)**

Line 37: On the basis of or Based on….  

The authors should combine some sentences. (lines…37 - 42)  

**The sentence has been changed (line 37-42)**

Line 44: European legislation or European Rules  

**We prefer European legislation**

**INTRODUCTION**

There is a disconnect in several parts in the section.  

**Introduction has been revised**

Line 55: the Authors may delete "significant" in the text.  

**Significant has been deleted (line 54-55)**

Lines 106-110: The Authors should explain better these sentences.  

**The classification of Hartwich, 1974 was based on the structure of the secretory-excretory system while that of Fagerholm, 1991 was based on the male caudal morphology (see table below from Murrell, K. Darwin, and Bernard Fried. Food-borne parasitic zoonoses: fish and plant-borne parasites. Vol. 11. Springer, 2007 report two different accepted classification for ascaridoid). These differences in the morphological characteristics used for phylogenetic**
reconstruction led to an array of contrasting interpretations and hypotheses of relationships, in turn leading to instability of ascaridoid classification, although the classification schemes of Hartwich (1974) and Fagerholm (1991) have been the most commonly used. Molecular data have been used to investigate phylogenetic relationships in the superfamily Ascaridoidea (e.g. Nadler, 1992; Nadler and Hudspeth, 1998, 2000; Zhu et al., 1998). Although these studies have not fully resolved taxonomic uncertainty within the superfamily, they tend to support the classification proposed by Fagerholm (1991). For this reason we decide to report the classification of Fagerholm, 1991, which consider the genus Hysterothyacium not belonging to the family Anisakidae, but to the family Raphidascariidae. A new section has been added in the text (Line 82-89).

Line 152: (Genchi and Pozio, 2003 before Abe, 2008)

Done Line (169)

Lines: 164-170 and: these sentences are not clear, Please could you explain these sentences better? I think that this sentence is not pertinent for the topic of the review.
The sentence has been modified and shortened (line 178-184)
Lines 192 - 193: the authors should eliminate this part.

The sentence has been modified (line 195-197)
Line: 202….the reference?

The reference has been refined (line 211)
Lines: 215-220 The objectives need to be re-written

The objectives have been re-written and moved at the beginning of the introduction (line 62-67)

LEGISLATIVE HYSTORY
Lines: 249-254 The authors should combine this part.

The sentence has been modified (line 242-249)
This is not in contrast with the EFSA opinion.

The reviewer did not report the line. Probably he/she refers to line 414 (original manuscript). The sentence has been modified according to the suggestion (line 393-395)

DISCUSSION
The Authors need to rethink the Discussion.
In my opinion this section is too long and the Authors may cut some parts or combine some sentences.

Discussion has been revised and shortened
Lines: 450-452…this part is not clear, the Authors need to rethink the sentence.

The sentence has been modified (line 427-428)
There is a disconnect in several parts in the section…please could you organize it better?
In some parts, I have found the same information reported in other sections (Introduction or Legislative History)

The section has been revised and the repeated information have been deleted

Reviewer #3: The paper gives an comprehensive overview on the European legislation concerning Anisakis in fish as food and describes in detail how the visual inspection was adopted in Italy. It needs some revisions before it is acceptable for publication.

In the introduction you should add a short paragraph on the ongoing debate on the necessity of larvae being alive to induce allergy the first time.
The section has been modified and some information has been reported on this issue (line 134-154)

line 130 - 141: the paragraph should be changed because Anisakis larvae can be found in most marine species caught in European waters and not only in the species you mentioned, e.g. herring can also be heavily infected.

According to the suggestions we decided to remove the paragraph from line 137 to line 141 (original manuscript) which is not fundamental for the aim of our review. This to avoid to add an excessive number of references, due to the fact that a multitude of fish species can be infected by Anisakids.

It is correct that according to the RASFF data, the species you mentioned are the most frequently parasitized species, but these species were mainly imported to Spain and Italy, other European countries simply do not check for nematodes in species landed in their harbours. So a general ranking could be different.

The sentence has been modified highlighting that the data mainly come from Italian and Spanish notification (Line 116-123)

line 142-148: This paragraph should be moved and included in the explanation given in line 176 - 185.

In this section we discussed the reason why the Anisakidosis is an emerging parasitosis and the factors that have led to an increase of the human cases of parasitosis. Among these factors, there is the decrease of INTERMEDIATE hosts of the larvae. The paragraph previously included in lines 142-148 is about the prevalence of infected species, which is higher where cetaceans are more numerous. This is an issue correlated more to the epidemiology of the infected species than to the increase of parasitosis cases in these last years. Therefore, we think that it should be included in the paragraph 1.1.

line 208-9: it was also my opinion that farmed Salmo salar presents an irrelevant risk of infestation, but Mo et al: Journal of Fish Diseases 37, 135-140 (2014) showed the farmed S.salar can be infected with Anisakis. So your conclusions throughout the paper concerning farmed salmon should be slightly revised according to this new findings.

The section about farmed salmon has been modified in the light of the results of Mo et al., 2014. Moreover, to avoid repetition, the section has been deleted from introduction and moved to line 450-457).

line 490 - 495. Anisakis free does not mean parasite free (trematodes, cestodes). It would be nice if you could add one sentence on possible consequences the consumption of fresh raw fish may have concerning these parasites.

A new sentence has been added at line 468-469
The presence of Anisakids larvae in fishery products is an emerging issue.
We carried out a survey on European and local laws on Anisakis risk management.
We analyzed the approach of different control systems to face the Anisakis risk.
The management of the Anisakis risk show differences in local laws.
A reassessment of the Anisakis issue is needed to yield common strategies.
Evolution of the Anisakis risk management in the European and Italian context.

ABSTRACT

Due to the social and legislative implications, the presence of *Anisakis* spp. larvae in fishery products has become a concern for both the consumers and the official Control Authorities. The issuance of a large number of provisions, aimed at better managing fish products intended to be consumed raw or almost raw and the associated risks, resulted in a very complicate legal framework. In this work, we analyzed the evolution of the normative through an overview on the local and international legislation, focusing on issues that are of practical interest for Food Business Operators (FBOs) in the fishery chain. In addition, we performed a survey across the Departments of Prevention of the Italian Local Health Authorities (LHA) and the main fish markets in Italy to collect the operating procedures and the monitoring plans. Overall, we found many differences, due to the absence of a national reference standard for the management of the *Anisakis* risk. From this examination, it turns clear that only a participation of all the involved Institutions, a strategy of synergistic interventions, as well as a correct training of FBOs, can result in an effective risk management and a proper risk communication, which should overcome states of confusion and unnecessary negative impacts on the economy.

Keywords: Anisakids, risk management, European legislation, raw fish products.
1. INTRODUCTION

Parasitic infections associated to the consumption of fish products have always been a concern for the public health and for economy. Recently, the World Health Organization (WHO) has estimated a prevalence of approximately 56 million cases worldwide and a population exposed to the risk of about 400 million individuals (World Health Organization, 2013). The main food-borne zoonoses associated with the consumption of fishery products are mainly attributable to trematodes, cestodes and nematodes. Among the latter, the Anisakids are the most important parasites from a sanitary point of view, since capable to induce pathologies in humans (Chai, Darwin Murrell, & Lymbery, 2005).

In this work, we made an excursus on the European, Italian and regional legislation and analyzed the operating procedures and the monitoring plans for prevention and control of Anisakidosis, the information on which were provided by the Italian Local Health Authorities (LHA) or collected at the main fish markets. We then highlighted the peculiarities in the current normative and the differences in the risk management strategies, implemented by the Official Authorities and by the FBOs.

1.1. Anisakids: classification, biological cycle and epidemiology

The identification of Anisakid species is very difficult due to the limited species-specific differences in morphological characters. Moreover, these differences are only visible in the adult worm and not in the larvae (Fagerholm, 1991; Mattiucci, Abaunza, Damiano, Garcia, Santos, & Nascetti, 2007). For this reason, in the past, only two species were considered responsible for zoonotic forms: *Anisakis simplex*, known as “herring worm”, and *Pseudoterranova decipiens*, known as “cod worm” (Smith and Wootten, 1978a; Murrell and Fried, 2007). However, the molecular studies based on genetic markers have shown that many morphospecies of *Anisakis* and *Pseudoterranova* include a certain number of sibling species with identical morphology, but different genetic make-up and geographical location (Mattiucci and Nascetti, 2008). Currently, 9 species of the *Anisakis* genus, (Mattiucci and
Nascetti, 2008; Mattiucci et al., 2011) and 6 of the Pseudoterranova genus (Paggi et al.,
1991; Mattiucci et al., 1998; George-Nascimento and Urrutia, 2000; McClelland, 2002;
Murell and Fried, 2007; Mattiucci and Nascetti, 2008) have been described.

Even though the taxonomic uncertainty within the superfamily has not been still
completely solved, the molecular analyses used to investigate phylogenetic relationships tend
to support the classification proposed by Fagerholm (1991) based on the male caudal
morphology (Murell and Fried, 2007). This classification considers the genus
Hysterothylacium not to belong to the family Anisakidae, but to the family Raphidascarididae.

In spite of this, there is a tendency to use the term Anisakidosis also for infections provoked
by species belonging to this genus, because likewise hazardous to public health (Audicana, et
al., 2002; Genchi and Pozio, 2003; Griglio et al., 2012).

The Anisakids are characterized by different stages of larval development, located in
different hosts. In general, the adult forms are located in the stomach of marine mammals,
while the eggs are shed in the feces and require an incubation period before hatching into
second stage larvae (L2). The L2 are ingested by invertebrates, especially crustaceans, such as
Euphausiacea and Copepoda, where they grow inside the hemocoel (McClelland, 2002;
Murell and Fried, 2007; Smith and Snyder, 2005). These larval forms do not seem to be
hazardous to the human health as it is the third stage larvae (L3), which, after being ingested
by a paratenic host, can directly encyst in the edible tissue (Nagasawa, 1990; Anderson and
Anderson, 2000), representing a risk when fishery products are consumed raw or
undercooked. In addition, some studies have shown that L3 larvae are able to migrate from
the viscera to the muscle, even after the death of the fish (Van Thiel, 1962; Smith and
Wootten, 1978a; Adams, Murrell, & Cross, 1997; Abollo, Gestal, & Pascual, 2001; Murrell
and Fried, 2007; Rello, Adroher, Benitez, & Valero, 2009; Pravettoni, Primavesi, &
Piantanida, 2012).
At the global level, the Anisakis larvae were found in at least 200 different species of fish
and 25 species of cephalopods (Abollo, Gestal, & Pascual, 2001; Klimpel, Palm, Rückert, &
Piantkowski, 2004; Murrell and Fried, 2007). In the Mediterranean Sea, the L3 larvae were
observed in 31 different species out of 99 species examined belonging to 47 families (about
15,000 specimens), with a prevalence ranging from 1.3 to 100% and with an infection
intensity from 1 to over 300 larvae per specimen (Ponzio, 2004). Moreover, some studies
have found that fishes caught in areas with abundant populations of cetaceans show a greater
degree of infection. For instance, in the Ligurian Sea, which is part of the Marine Mammal
Sanctuary and where the presence of whales and dolphins is stable, the prevalence of infection
is 5 times greater than those found in the South Atlantic or in other Mediterranean areas
(Notarbartolo-di-Sciara, Agardy, Hyrenbach, Scovazzi, & Van Klaveren, 2008; Rello et al.,
2009).

In the European Union, in the period 2009-2013, the Rapid Alert System for Food and
Feed (RASFF) (Rapid Alert System for Food and Feed, 2014) has reported a total of 333
notifications for the presence of parasites: of these, 262 (78.5%) were due to Anisakis spp.
These notifications were mainly forwarded by Italy (147) and Spain (49) and refer to 108
border rejections, 86 information and 68 alerts. The RASFF data, mainly based on Italy and
Spain notification, show that the most frequently parasitized fish, among the species
commercialized in this countries, were: Merluccius merluccius, Scomber scombrus, Engraulis
engrasicolus, Lophius spp., Xiphias gladius and Lepidopus caudatus.

1.2 Human health issues

In 1988, Kassai et al. recommended the use of three different terms to indicate zoonoses
caused by nematodes of the Anisakidae family:

- Anisakidosis: for zoonoses from species belonging to the Anisakidae family (Anisakids);
- Anisakiosis: for zoonoses from species belonging to Anisakis genus;
- Pseudoterranovosis: for zoonoses from species belonging to the Pseudoterranova genus.
Humans, who are accidental hosts of the L3 larvae, may develop diseases, which presents either non-invasive forms, generally asymptomatic, or invasive forms, characterized by gastrointestinal symptoms (acute or chronic), nowadays well identified and extensively described and discussed in the literature.

What is less known is the “gastroallergic anisakidosis”, an IgE-mediated allergic reaction that can be developed after ingestion of Anisakids. It is characterized by clinical manifestations ranging from urticaria to anaphylactic shock (Daschner, Alonso-Gomez, Cabanas, Suarez-de-Parga, & Lopez-Serrano, 2000; Dominguez-Ortega et al., 2001). Despite two episodes of allergy have been described without the involvement of living parasites (Audicana et al., 1995; Aníbarro et al., 1997), the ingestion of alive larvae is usually required for sensitization and allergic reactions (Daschner, Alonso-Gomez, Cabanas, Suarez-de-Parga, & Lopez-Serrano, 2000; Audicana, et al., 2002; Alonso-Gomez et al., 2004), while the exposure to Anisakis proteins alone may suffice to elicit allergic reactions in sensitized individuals (Nieuwenhuizen et al., 2006). This possibility makes the “gastroallergic anisakidosis” a professional pathology in people who have frequent contacts with infected fish (Aníbarro et al., 1997; Aníbarro and Seoane, 1998; Armentia et al., 1998; Scala et al., 2001). Still, considering that some allergens have been shown to be heat-resistant, cooking might not provide an effective protection against allergic manifestations (Moneo, Caballero, GómezOrtega, & Alonso, 2000; Caballero and Moneo, 2004; Moneo et al., 2005). For instance, it has been reported that in northern Spain the consumption of cooked hake is one of the main cause of allergies, closely followed by cooked or raw anchovies (Fernández de Corres et al., 1996; Audicana, Del Pozo, Iglesias, & Ubeira 2003). On the contrary, it has also been reported that freezing could reduce the risk of allergic reactions (Garcia et al., 2001). However, the exposure to Anisakid antigens is still a debated issue, due to the many clinical manifestations that are involved (Audicana and Kennedy, 2008).
The 90% of diseases related to the ingestion of Anisakids worldwide is determined by *Anisakis simplex*, *A. pegreffii* and *Pseudoterranova* spp. (Bouree, Paugam, & Petithory, 1995; Rosales et al., 1999; Smith, 1999; Audicana, *et al.*, 2002; Murrell and Fried, 2007). In Italy, the species most frequently associated to health issues is *A. pegreffii* (D’Amelio, Mathiopoulosv, Brandonisio, Lucarelli, Doronz, & Paggi, 1999; Moschella *et al.*, 2004; Fumarola *et al.*, 2009; Mattiucci *et al.*, 2011; Bernardi, Gustinelli, Fioravanti, Caffara, Mattiucci, & Cattaneo, 2011; Mladineo and Poljak, 2013). *A. physeteris*, *Contracaecum* spp. and *Hysterothylacium* spp. are other species of *Anisakis* spp. that can be involved in human infections, even though they are only seldomly involved in pathological forms (Ishikura *et al.*, 1993; Yagi *et al.*, 1996; Rosales *et al.*, 1999; Smith, 1999; Lima dos Santos and Howgate, 2011).

### 1.3 The oxymoron of Anisakidosis: a classic but emerging parasitosis.

In the last decade there have been about 20,000 cases of human Anisakidosis, of which more than 90% located in Japan, where, every year, about 2,000 infections occurs (Genchi and Pozio, 2003; Abe, 2008). In the United States, a recent survey of patients with generic gastrointestinal disorders showed that these symptoms were ascribable to parasitic diseases of fish origin, with such a frequency to require preventive controls throughout the national territory (Hochberg, Hamer, Hughes, & Wilson, 2010).

In Europe, the estimated incidence is about 0.038% (Orphanet, 2009 and Lima dos Santos and Howgate, 2011). Most of the cases have been registered in Spain, Netherlands and Germany, (European Food Safety Authority, 2010 and Pravettoni, Primavesi, & Piantanida, 2012). The exact incidence is difficult to establish, but it seems to average 20 cases per country per year. In France, a report of 2003 estimated an incidence of eight cases per year (French Agency for Food, Environmental and Occupational Health and Safety, 2011). In Italy, 54 cases had been reported from 1996 to 2011 (Ponzio, 2004; De Rosa, 2011; Griglio *et al.*, 2012), most of which occurred in Puglia, Abruzzo, Molise and Sicily, especially in coastal
areas. Only few sporadic cases have been reported in other regions as Emilia Romagna, Ligury, Lombardy, Tuscany, Marche, Lazio and Campania. All cases were associated with the consumption of traditional dishes made with anchovies, herring and mackerel served raw or "almost raw" (Ponzio, 2004; De Rosa, 2011; Griglio et al., 2012).

The factors that have led to an increase of the Anisakidosis cases over the past 30 years are many and interdependent. First of all, the food scare crises, such as the “mad cow disease” and the “avian influenza”, which have shifted the orientation of consumers’ attention towards proteins of fish origin, have increased the consumption of fishery products.

Another factor to be taken into consideration is the spread of ethnic food on the Western tables has led to the availability of a variety of Oriental dishes, especially Japanese, characterized by preparations of raw seafood. In fact, many Japanese restaurants are not really authentic, but managed by operators of different ethnicity, especially Chinese. These latter tend to increasingly convert their restaurant activities into Sushi Bars or Sushi Restaurants, offering cheaper products, often at the expense of quality (Masotti, Amadei, & Lanni, 2010; Armani, Castigliego, Gianfaldoni, & Guidi, 2011). However, the lack of a proper knowledge on the microbiological and parasitic risks associated to dishes based on raw fish could lead to an inappropriate manipulation and treatment of the raw materials.

Not to be undervalued is also the change, in recent years, of the control responsibility in the fishery chain. In fact, while once the veterinary inspector was the person in charge for controls, nowadays, this task is delegated to the FBOs, who are not always adequately trained in detecting infections.

Finally, the unconditioned increase in the supply of wild fishery products has often determined adverse effects on the availability of natural fisheries, resulting in a depletion of marine resources. Therefore, the reduction of the species that have "historically" represented the intermediate hosts, together with the low specificity that these parasites have towards their intermediate hosts (Lymbery and Cheah, 2007; Murrell and Fried, 2007), have likely
determined the progressive increase of both the number of affected species and the prevalence
of infection.

Due to the increasing difficulties in the management of the "Anisakis risk", related to the
involvement of wider geographic areas and to the significant number of individuals affected
by anisakidosis, the European Food Safety Authority (EFSA), in its report (EFSA, Panel on
Biological Hazards (BIOHAZ), 2010), highlighted that no maritime area can be considered
free from Anisakids and that the presence of larvae in fishery products is a natural condition
that claims the "presumption of infection" throughout the supply chain. In conclusion, the
group of EFSA experts stated that to reduce Anisakis infection it is essential to provide to all
the operators involved in the fishery chain and to the final consumers the necessary
information for the proper management of the risks associated to the presence of parasites in
fishery products.

2. LEGISLATIVE HISTORY

2.1. Before the “Hygiene Package”

In Europe, the first regulation related to the management of the Anisakis spp. associated
risk was issued by the Dutch Health Authorities in the years 1968/69. This law allowed the
marketing of not-eviscerated herrings only if previously subjected to treatments for
devitalization of the larvae (Panebianco and Lo Schiavo, 1985).

In the early 70's, in Germany traders and processors decided to adopt the regulations issued
by the Dutch Authorities (Horst, 2008) but, in the course of the '80s, some companies decided
to no longer adhere to this voluntary agreement. This led to an increase of cases of infection
and to the collapse of sales. Since then, the German government started a series of efforts in
order to minimize the Anisakids risk in the domestic fish products (Horst, 2008). On August
the 8th 1988, the Federal Republic of Germany issued an Ordinance (Federal Republic of
Germany, 1988), which ordered the removal of parts containing nematodes (dead or alive)
and their marketing ban.
In the same period, both the French and the Dutch Ministry of Agriculture and Fisheries instituted specific rules for herrings processing (Renon and Malandra, 1991). In Italy, the first specific Circular Letters (CL) on Anisakis were enacted around the 80’s, but already in 1962, with the national Law n.283, it was forbidden to “use in the preparation of food or drink, sell, hold to sell, administer or otherwise distribute for consumption, soiled, invaded by parasites, altered or harmful foodstuff”. The parasites considered by the Law n. 283 were not Anisakids, but all those that could be found in the products, as a consequence of a poor state of preservation and thus destined to seizure and destruction.

The first specific legislation on the management of Anisakis spp. in fishery products was enacted in 1992, when the presence of the parasite strikingly emerged in bluefish. In order to draw the attention of the industry, consumers and Health Authorities on the need to adopt systems to prevent this zoonosis, the CL No. 10 of 11/03/1992 was issued by the Ministry of Health: the Italian government recommended the FBOs to proceed with a rapid evisceration of the fish at risk of infection (with a size exceeding 18 cm) and not to throw the entrails into the sea. On the other hand, the veterinary inspectors were asked to carry out a check of the fish through random sampling and visual inspection, after opening the coelomic cavity (Circular Letter No. 10/92). Finally, if the invasion by the parasites of the edible parts was such as to give a repugnant appearance to the fish, according to the judgment of the veterinary inspector, the Letter No. 10 settled the obligation to destroy the products. In case of slight infection, the veterinary inspector could instead dispose the treatment of products to kill parasites. Such treatment consisted in the freezing at -20 °C for at least 24 hours or, alternatively, in the heat treatment at 60 °C for 10 minutes at least. As for the visual inspection, the aforesaid Letter did not include particular obligations for the retailers, but a verification that the product had been monitored by the Veterinary Service. These provisions were resumed in the Ministerial Decree of 12/05/1992, which stated that preventive
treatments would have been only carried out in authorized establishments and that they had to be certified (Ministerial Decree of 12/05/1992).

Subsequently, the Legislative Decree No. 531 of 30/12/1992 introduced the obligation of the visual inspection and the research of visible parasites, before the introduction on the market. The Decree No. 531 also ordered that the fish or their parts, obviously infected with parasites, were not intended for human consumption. Fishes, to be consumed raw or almost raw, cold-smoked (with a core fish temperature of less than 60° C), as well as marinated and/or salted, had to be treated with low temperatures if the process did not guarantee the death of the larvae (Decreto Legislativo No. 531/92).

In 1993, Commission Decision No. 93/140/EEC defined the concept of "visible parasite" as "a parasite or a group of parasites which has a dimension, color or texture which is clearly distinguishable from fish tissues" and "visual inspection" as "a non-destructive examination of fish or fishery products without optical means of magnifying and under good light conditions for human vision, including, if necessary, candling". The recipients of the aforesaid Decision were required to implement controls for the detection of visible parasites in whole products and in fish fillets or slices. They must determine the scale and frequency of the inspections, depending on the nature of the fishery products, their geographical origin and their use. For eviscerated fish, the search for visible parasites must be conducted by professionals on the abdominal cavity, livers and roes, intended for human consumption. According to the type of evisceration, the visual inspection must be performed in a continuous manner at the time of evisceration and washing (manual evisceration) or by sampling a representative number of specimens, being not less than 10 fish per batch (mechanical evisceration). Fish fillets and fish slices must be inspected by qualified personnel during trimming after filleting or slicing. Where an individual examination is not possible, due to the size of the fillets or to the filleting operations, operators must draw up a sampling plan.
In later years, some Italian regions introduced appropriate measures into their local legislation, in order to protect the health of the consumers. In 1994, the Region of Lombardy defined the procedures for carrying out a statistically significant sampling for the detection of the parasite in fish products (Table 1). The protocol established that, through an initial visual inspection, the Control Authority must ensure that there were no migrating larvae on the outer surface of the fish. Otherwise, the lot of fish should have been withdrawn and subsequently destroyed. As for the anchovies, if no larvae were found on the surface, the Authority would have proceeded with the sampling, on a representative number of specimens, according to the "Table of statistical significance" (Table 1). In 1997, the Liguria Region stated that in all business activities where raw anchovies were commercialized, an informative billboard must have been displayed reporting "...the specimens of anchovies (Engraulis encrasicolus) used in food preparation as raw, raw marinated “the flagship acciughette” or with lemon etc., must be previously frozen at -20 °C for at least 24 hours" (Decree of the President of the Regional Council n. 282/49671). Moreover, the Liguria Region defined how the controls must be carried out on lots of anchovies, as well as the appropriate measures to be taken following the outcome of the inspection. In particular, specific procedures were defined for the sampling of specimens (Circular Letter No. 1 of 1997).

In 1996, an European Regulation took into consideration, for the first time, the relationship between the presence of parasites and the negative effect that they have on the quality of the product, establishing the downgrade of the products despite the excellent organoleptic conditions and the favorable judgment of edibility (Council Regulation (EC) No. 2406/96).

In 1999, the Norwegian Directorate of Fisheries, on the basis of the European rules, established that a visual control of random samples must be carried out to detect and remove visible parasites. The controls must be performed after gutting and rinsing of the belly cavity and any liver/roe and during filleting and slicing, possibly using the candling. The person in charge of the establishment would set up a plan, as part of the self-monitoring, specifying the
scope and frequency of the controls in relation to the type of product, geographical origin and use. Herrings, mackerels, sprats, wild salmons caught in the Atlantic or Pacific Ocean, marinated and/or salted herrings (when the treatment has not been sufficient to destroy nematode larvae) intended to be eaten raw or almost raw, must undergo a freezing treatment at a core temperature of -20° C or lower for at least 24 hour. Moreover, the fish species listed above, if not sold as fresh or frozen products, must be accompanied by a certificate from the producer indicating the type of treatment that they had undergone. Finally, special provisions were required for packed capelin roe, which must, on examination of a minimum of 6 samples, contain a maximum average of 1 nematode larva per 100 g in the samples, and a maximum of 3 nematode larvae per 100 g in any single sample (Norwegian Directorate of Fisheries, 1999).

2.2. After the “Hygiene Package”

The new provisions introduced by the “Hygiene Package” led to a radical change in the system of parasites control in fishery products. At the fish market, the figure of the official veterinarian, who was previously responsible for carrying out the sampling and the visual inspection of the fish, has been replaced by the FBO, who has become the first responsible for the risk management. The FBO is required to set, implement and maintain the procedures based on HACCP principles (Hazard Analysis Critical Control Points), through an analysis of risks associated with food production. He should also identify operational techniques to eliminate or reduce the presence of Anisakids in the finished product. Unfortunately, the new regulatory approach does not define the specific methods and procedures that the FBOs have to apply, but it only defines the objectives that they have to attain, possibly assisted by the Competent Authorities. This transposition of tasks, if on one side has streamlined the official inspection practices, on the other implies an adequate training of FBOs. In fact, at present, the FBOs are called to perform a statistically significant and appropriately documented sampling, in order to demonstrate that they have taken all possible precautions to detect parasites. Such
a sampling should be performed by qualified persons, who are required to submit their
products to a control for the detection of visible parasites, without placing on the market those
‘obviously contaminated’.

The Regulation (EC) No. 853/2004 states that fishery products to be consumed raw, almost
raw, marinated, salted and cold smoked with an internal temperature not more than 60° should
be frozen at a temperature not higher than -20 °C in all parts of the product for at least 24
hours. Subsequently, Regulation (EC) No. 2074/2005 gave further explanations about the
visual inspections, clarifying the concept of candling: “Candling means, in respect of flat fish
or fish fillets, holding up fish to a light in a darkened room to detect parasites”.

In 2006, in Spain, the Royal Decree 1420/2006 was issued, following both the EU policies
and the data provided by the Scientific Committee of the Spanish Agency for Food Safety
(AESAN) and the National Center for Epidemiology, which showed a higher incidence of the
parasite in fish and an increase in Anisakidosis prevalence in the population. With this Decree
all the operators dealing with preparation and catering activities were called to accomplish a
preventive treatment of fishery products to be consumed as raw or almost raw, cold-smoked,
pickled or salted. Afterwards, in 2007, the AESAN provided some recommendations
concerning the best criteria to determine if freezing is necessary in marinated or salted fish
products (Comité Científico de la Agencia Española de Seguridad Alimentaria y Nutrición,
2007).

In May 2008, the Italian Ministry of Health, following the remarks received by the
European Commission about the activation procedure of the national alert system for the
detection of Anisakis spp. in fishery products coming from Third Countries, issued the CL
DGSAN No. 10776-P. This document provided that the alert system must be activated only
after detection of viable larvae in the coelomic cavity and in the flesh of fresh fish products or
in those products subjected to heat treatment insufficient to kill larvae. Moreover, if during
controls, products unsuitable for human consumption were found (regardless of the larvae were dead or alive), the authorities should proceed with the rejection of the goods.

Moreover, in 2008, with the amendments introduced by Reg. (EC) No. 1020/2008 to the Reg. (EC) No. 853/2004, the visual inspection become mandatory also for FBOs who operate at the retail level.

In Italy, following the EFSA opinion of 2010, the Ministerial CL 4379-P and 4380-P of 17/02/2011 were enacted. The Letter 4379-P-17/02/2011 stresses the obligation for FBOs to freeze at a temperature not higher than \(-20 \, ^{\circ}\text{C}\) and for almost 24 hours, the fish (even fresh water fishes) intended to be administered raw. The type of the treatment must be declared in the self-monitoring plan of the food business activities and, the fishery products always be accompanied, during their placing on the market, by a certificate of the FBO, stating the treatment performed. Moreover, the Letter 4379-P, in order to maintain the correct information on freezing treatment and due to the fact that reporting the term “defrosted” on products previously frozen for health safety purposes might negatively influence the consumer, allowed to report: ”Conforms to Regulation EC No. 853/20054, Annex III, Section VII, Chapter 3, point D, point 3” on products label.

The Letter 4380-P1 stated that, if in presence of infected products, the operators prove they acted in good faith and in accordance with the law the theory of liability is not "perfectible" against them and therefore the Article 5 of Law 283/62 is not applicable. Before this CL, due to the numerous detections of *Anisakis* spp. in fishery products, the Regional Directorate of Public Health of Piedmont Region issued, in 2010, the Note No. 16294. This note established that retailers "... have to communicate to the local competent authority the detection of viable larvae found during self-monitoring and selling".

In 2011, in Europe the Reg. (EC) No. 1276/2011 was issued, which amended and expanded the Annex III of Regulation (EC) No. 853/2004. The FBOs were called to respect the requirements also when place on the market "Fishery products derived from finfish and..."
cephalopod molluscs" (in the Reg. (EC) No. 853/2004 generically defined as "fish") at the retail or catering level. This clarification was necessary, considering that cephalopods, as already stressed above, may be infected by Anisakids. Moreover, according to this Reg., the freezing treatment should be aimed at killing the "viable parasite" and not the "nematode larvae", as defined by Reg. (EC) No. 853/2004. Furthermore, for parasites other than trematodes, the new provisions introduce the possibility to apply other time/temperature combinations for the freezing treatment, such as -35° C for at least 15 hours.

According to the new provisions, the FBOs can place on the market fresh and not treated fishery products only if they are intended for cooking or if they come from fishing area and/or “Anisakis free” farms. However, the FBOs must ensure that the fishing or aquaculture area of origin are in conformity with the requirements of Reg. (EC) No. 1276/2011, through a check of the information provided by the accompanying documents. In fact, as previously stated by the CL 4379-P, if the freezing treatment is carried out in the intermediate steps of the product chain, the FBO supplier is obliged to provide to the buyer a certificate that states the freezing method applied. In 2011, both the Piedmont and Puglia Regions, with the Note Circular No. 2998 and 8499, respectively, tried to clarify some aspects of application of Reg. (EC) No. 853/2004 regarding the sale and supply of fishery products. In particular, both notes pointed out the role of the FBOs and their responsibility for visual inspection, to be carried out for self-monitoring and during the sales activities, stressing the importance for the operators to record all the non-conformances detected and the corrective actions taken.

In 2012, at the Italian national level, the Ministerial Note DGISAN 0024111-P drew attention to the official control of parasitic infections, reaffirming that it represents an effective measure for the risk management during the marketing and administration of fishery products. Subsequently, the Italian Decree No. 158/2012, known as "Balduzzi" Decree, ordered that: "The food business operator, who offers for sale to the final consumer fresh fish and cephalopods as well as products of fresh water, ........ is required to expose a clearly
visible billboard bearing the information specified by the Minister of Health, after consultation with the Minister of Agriculture and Forestry, concerning the correct conditions of employment”. Recently, this provision has been further specified by the Decree of July 17, 2013 of the Italian Ministry of Health, which stated that, at the retail level, a billboard should be displayed in a prominent position reporting: "In case of consumption as raw, marinated or not fully cooked, the product must first be frozen for at least 96 hours at -18 ° C in a domestic freezer marked with three or more stars”.

In order to facilitate understanding, the laws related to the standards considered in this work are listed in chronological order in the Table 2.

3. DISCUSSION

The different geographical origin, species and size, method of capture, and post-capture operations are among the main factors that could influence the chances of fishery products to be contaminated by Anisakids larvae. On the other hand, good manufacturing practices and HACCP programs, applied from the primary production to the administration and/or use by the final consumer, are the two key factors to maximize the safety of fishery products, reducing the Anisakis spp. risk to acceptable levels. However, in our opinion, some points should be pointed out to better understand the risk management of this zoonoses.

3.1 Preventive pre-capture measures.

The preventive measures that FBOs can apply before the capture are very limited and are mainly related to farming. In fact, only sometimes there is the possibility to raise "Anisakis free" fish, through the implementation of management procedures, validated by the Competent Authority and aimed at controlling the environmental and ecological factors that regulate the relationship between hosts and parasites (French Food Safety Agency, 2007).

One of the factor to be taken into account is the feeding plan. As reported by Reg. (EC) No. 1276/2011, after the approval by the Competent Authority, fishery products raised exclusively in free area and fed with a diet without parasites can be considered exempt from
Anisakis spp. In particular, it is essential that the farmed fish are not fed with wet fee, but only with pellet (U.S. Food and Drug Administration, 2013). The geographical location is another important factor to be considered. In this context, epidemiological studies in marine areas of interest, aimed at assessing the level of infection of the species are a prerequisite to the installation of the farm.

Despite Peñalver et al. (2010) reported the absence of Anisakids larvae in sea bass, EFSA, based on scientific data examined (Deardorff and Kent, 1989; Angot and Brasseur, 1993; and Inoue, Oshima, Hirata, & Kimura, 2000; Lunestad, 2003; Wootten, Yoon, & Bron, 2009; Lima dos Santos and Howgate, 2011), asserted that the risk of parasites can be considered negligible only for Atlantic salmon (Salmo salar) and that the possibility that parasites may also affect farmed fish grown in open sea must not be underestimated. In fact, it is possible that invertebrates and fishes could enter into the cages and transfer the parasite to the species farmed (Marty, 2008; Skov, Kania, Olsen, Lauridsen, & Buchmann, 2009). However, a recent work of Mo et al. 2014, reported the presence of A. simplex and H. aduncum both in viscera and in muscle of farmed Atlantic salmon (Salmo salar). However, the larvae have been only found in runts not processed for human consumption. Therefore, even though these observations should be considered in future risk analyses, currently, the risk of infection for the Atlantic salmon farmed in floating cages or onshore tanks and fed with feed that does not contain live parasites can be considered irrelevant (Marty, 2008; European Food Safety Authority, 2010; Norwegian Food Safety Authority, 2011).

In Spain, a research project conducted during 2011-2012 showed that national aquaculture products, such as sea bass, bream, turbot and Croaker are free of Anisakis spp. larvae (Asociación Empresarial de Productores de Cultivos Marinos, (APROMAR), 2012). It is not to be rejected the hypothesis that, in this Country, these species could be marketed without the need to apply the preventive freezing treatment. In Italy, only the Region of Puglia has indicated cases of exclusion from the obligation of freezing treatment, in relation to the local
culinary habits and to the frequent consumption of raw or marinated fish products in its own
territory. The possibility to obtain "Anisakis free" products, would not only avoid the freezing
treatment, but also allow the sale of a fresh product, characterized by a better commercial
appeal.

However, considering that “Anisakis free” does not mean “parasite free”, the presence of
some other kind of parasites, such as trematodes or cestodes, cannot be excluded a priori.

3.2 Preventive post-capture measures

3.2.1 Fish handling on board. Since no fishing area can be considered free from zoonotic
parasites (European Food Safety Authority, 2010), the only post-capture measure that can
reduce, or rather, not increase the spread of the parasitic infection is related to good
manufacturing practices on vessels. In particular, in order to break the cycle of the parasite, it
is crucial not to dispose the entrails into the sea. With this regard, the Reg. (EC) No.
1069/2009, "laying down health rules as regards animal by-products and derived products
not intended for human consumption…", clarifies specific measures for the disposal of
materials derived from evisceration of fish with signs of disease on board fishing vessels. It
follows that the fish parasitized by Anisakis spp. must necessarily be regarded as Category 1
material. In fact, the Article 8, paragraph a), makes clear reference to "wild animals, when
suspected of being infected with diseases communicable to humans or animals".

3.2.2 Inspection control. During inspection controls, the possible infection in fishery
products can be detected by non-destructive or destructive methods. The first, such as visual
inspection and candling, can be used for gutted and filleted products, while, in case of whole
fish, inspection of the viscera can be performed by opening the coelomic cavity. The
enzymatic digestion (destructive method), despite more sensitive in identifying the parasites,
is not considered an official method, as a consequence of the small number of samples that
can be processed and to the long time requested (Karl and Leinemann, 1997). The visual
inspection method does not suffice to detect all the larvae, but only 50% of the parasites
detectable by other techniques, such as candling or enzymatic digestion (Llarena-Reino, González, Vello, Outeiriño, & Pascual, 2012). The U.S. FDA considers candling as a subjective technique (U.S. Food and Drug Administration, 2001), whose outcome can be affected by many factors, such as: thickness of the fillet, oil content, presence of skin, pigmentation, and training level and competence of the FBOs (Smith, 1999; Stormo, Sivertsen, Heia, Nilsen, & Elvevoll, 2007; Milligan, 2008; Angelucci et al., 2011). However, candling is considered an official method by the Codex Alimentarius (Codex Alimentarius Commission, 1995).

3.2.3 Sampling plans. Currently, no European or Italian legislation defines a statistically significant sampling system to be used for the collection of samples during the inspection. In this context, the sampling procedures for the visual search of the parasite often refer to the internationally accepted protocols, such as those of the Codex Alimentarius. Specifically, the Codex Alimentarius (Codex Alimentarius Commission, 1989) establishes that the presence of two or more parasites per kg of sample unit with a capsular diameter greater than 3 mm, or the detection of a parasite not encapsulated and greater than 10 mm in length, determine the non-conformity of the product. In addition, based on the requirements of the Codex sampling plans for prepackaged products (Codex Alimentarius Commission, 1969), Canada has set limits stating that, for batches of 1 kg or more, the presence of 2 or more parasites per kg of sample unit entails the rejection of the sample. In case of prepackaged products of less than 1 kg, the rejection is due to the detection of 1 parasite per kg calculated on the total sample (Canada Food Inspection Agency, 2013).

In Italy, some Regions have set up specific procedure to look for the Anisakis spp. parasites in fishery products, especially focusing on anchovies. In 1994, the Lombardy Region provided a statistical method to be used for the detection of Anisakis larvae, which is still used. This protocol, developed for the veterinary inspector, but today also applicable by the FBOs, provides criteria for sampling of a statistically significant number of specimens to be
inspected, given a degree of sensitivity of 10% and confidence of 95%. From the total weight of the lot it is possible to estimate the number of specimens that compose it, using a conversion ratio, which differs depending on the species. Then, once the size of the lot has been determined, and given a sensitivity of 5 or 10%, it is possible to determine the number of subjects to be examined (Table 1). For the visual inspection, the head and viscera are removed from the body (edible portion) and left at room temperature for at least 10 minutes. In this way, the larvae start moving and become visible. The inspection procedure adopted by the Liguria Region is very similar, but the sampling of the specimens must be performed on the basis of the number of boxes (Circular Letter No. 1 of 1997). When the lot is composed of less than 10 boxes, 3 specimens per box (up to 28) were to be sampled, while from 10 to 150 boxes 1 specimens per box (up to 28), and for more than 150 boxes, 1 specimen per box (up to 40) (Tab3). A basic prerequisite, for a statistically representative sampling control, is that the lot is uniform with regard to the specimen size and origin. Furthermore, the larger the size, the greater the risk of infection.

Therefore, among the criteria for identifying the lots to be sampled it could be considered: fish species with higher Anisakis-related risk, geographical origin, commercial size and destination. In addition, it would be appropriate to conform the criteria of sampling by:

- ensuring the uniformity of the lot;
- considering the number of crates, carrying out sampling evenly distributed throughout the lot, taking samples at several points;
- collecting a statistically significant number of specimens;
- examining the viscera removed from the cavity and the cavity itself after 30/40 minutes after their evisceration and exposure.

The experience gained in decades of sampling shows that the degree of infection within a lot is constant and this allows to state that the visual examination of the viscera has a value statistically reliable for the purposes of a judgment. Therefore, it is possible to demonstrate a
directly proportional correlation between the number of specimens parasitized and the number
of larvae detectable: in general, to a high number of parasitized subjects corresponds a high
number of larvae per subject (and vice versa). Therefore, it is essential to identify the
percentage of parasitized subjects that can be tolerated, or rather the percentage that is not
perceptible to the observation of the consumer. For instance, on the basis of a confidence level
of 95% associated with the sampling method, there is the possibility that in 5% of cases the
10% of infected subjects (occult infection) may not be detected, a percentage of additional
tolerance of 10% could be proposed. This means that, during the inspection, it could be
tolerated the presence of up to a maximum of 3 parasitized subjects, up to a maximum of 3
larvae each, when the sampling presupposes the collection of the 29 specimens (lot> 600
specimens). For batches in which the percentage of parasitized individuals exceeds the level
of tolerability, the FBOs should choose the destination depending on the species, size and
final use.

In the other Italian regions, the provisions laid down are more or less those adopted by the
Regions of Lombardy and Liguria. Regarding Sardinia, the sampling is carried out in a
different manner depending on the size of the species. For instance, for specimens weighing
less than 20 grams, the procedure applied is the same as that applied in the Liguria Region for
anchovies. For species weighing more than 20 grams, new criteria have been established
(Table 3). Even in the Region of Marche, the Operating Unit (OU) for Fishing Products of the
LHA has developed a procedure similar to that provided by the Liguria Region (Tab3). The
procedure laid down by the Veneto Region provides that research for parasites must be
carried out only on fish at risk if they are intended for cold processing and if not previously
frozen (Tab 3). An interesting aspect to highlight is that, in case of non-compliance, the
procedure requires that at least the three successive batches from the same supplier must be
checked.
The procedures that must be put in place after the visual inspection are different in the two Regional laws. In this regard, it may be interesting to consider the weight of a hypothetical sample of anchovies. Based on the data provided by the CL of the Liguria Region, we can infer that a sample of 28-30 anchovies may have a weight ranging between 200 and 300 grams depending on the season. Therefore, the approach of the Lombardy Region seems to be more in line with the provisions of the Codex than with those of the Liguria Region, even though no distinction is made between encysted and free parasites. In fact, for a sample with a weight less than 1 kg, the entire batch should be rejected following the discovery of a single parasite. On the other hand, this procedure could be considered overly restrictive, whereas, at present, only the batches obviously infected should be subjected to restrictions on marketing. For this reason, the Veterinary Services of the Lombardy Region, and especially those present at the wholesale fish market of Milan, have adopted an approach that, while bestowing greater tolerance, allows to identify, at the same time, the lots manifestly contaminated.

As for the other Regions, Sardinia provides that batches invaded by clearly visible parasites should be seized and destroyed. In this regard, the Region of Marche states that the destruction of the consignment is to be carried out only in case of massive infection and repulsive appearance of the products, applying the same criteria adopted in Liguria (Table 3). Unfortunately, the expression “massive infection” is not easily correlatable to “obviously contaminated”, adopted by the European Commission to indicate a product not suitable for human consumption.

3.2.4 Obviously contaminated. The wording "obviously contaminated" introduced by Council Reg. (EC) No. 853/2004 has been the topic of several discussions in Europe. In fact, the European Commission has noted that the term "obviously" can be interpreted in different ways within each Member State. This led the Commission to produce the draft document SANCO/10137/2013-rev1. In this document, it is reported that a distinction should be made based on the location of the visible parasite. If during the visual inspection larvae are found in
the edible part, such as the muscles, the product is considered to be obviously contaminated.

If the visible parasites are found only in the non-edible parts, such as viscera, the raw material is not to be considered "obviously contaminated" and can be placed on the market.

Another concept closely related to the definition of "obviously contaminated" is that of "visible parasite". On the basis of the definition given by the Decision 93/140/CE and by the Codex Alimentarius (Codex Alimentarius Commission, 1971), the larvae must have a size that make them detectable and must be clearly differentiable from the tissues of the fish, even in the absence of optical instruments. In this regard, it must be underlined that the larvae of Hysterothylacium spp. (0.7 mm -2 cm) (Køie, 1993; Borges, Cuhna, Santos, Monteiro-Neto, & Santos 2012) can often co-infect fish together with the larvae of Anisakis spp. (10-30 mm in length and 0.44-0.54 mm in diameter) (Sakanari and McKerrow, 1989; Genchi and Pozio, 2003), from which are not easily distinguishable macroscopically. Thus, even though Hysterothylacium spp. are only rarely responsible for diseases, they fall within the concept of “visible parasite” and for this reason contribute to determine the total infection degree. On the basis of these findings, when talking about nematode larvae, it would be more appropriate to refer to visible larvae, including Anisakis spp. and Hysterothylacium spp., rather than about Anisakids larvae.

3.2.5 Processing that guarantee the inactivation of the parasites. At present, the freezing treatment can be also done at the retail level, such as catering establishments, restaurants and similar administration activities that have been registered under the current legislation.

In Italy, if the FBOs want to directly perform the preventive treatment, they have to provide the necessary guarantees of compliance and effectiveness (Ministerial Circular Letter 4379-P-17/02/2011). First, the FBOs, after setting up a written procedure aimed at controlling the presence of parasites based on the principles of the HACCP system, must give a prior communication to the Competent Authority concerning the preventive treatment to be applied. Then, they are required to be equipped with an appropriate blast chiller, certified for
the reduction of the temperature at -20° C, which must be exclusively used to perform the
freezing treatment and not to preserve fish or other product. About the freezing method, the
U.S. FDA stated that the effectiveness of the treatment is related to several factors, the most
important of which are the type of parasite involved, the temperature and the duration of the
treatment (U.S. Food and Drug Administration, 2013). Also, the time required to reach the
intended core temperature and the percentage of fat of the fish can affect the preventive
treatment. With regard to the type of parasite involved, it should be underlined that some
cestodes, for instance, are more sensitive to freezing than nematodes, which, however, are less
resistant than trematodes. According to the U.S. FDA (U.S. Food and Drug Administration,
2013), in order to kill the nematode parasite, the product may be subjected to various types of
preventive treatments, which provide different time/temperatures combination, such as:

- Freezing at -20° C followed by a storage period of 7 days at - 20° C (or lower);
- Freezing at -35° C (or lower) associated with a period of storage at -35° C (or lower) for
  15 hours;
- Freezing at -35° C (or lower) and at -20° C (or lower) for 24 hours.

The freezing, as preventive treatment, is a procedure expressly required by law and,
according the provisions about the correct information to consumer, the data related to the
process have to accompany the product up to the retail sale. However, this information is
usually omitted, especially in catering and food service. This is because the defrosted fish
creates mistrust among consumers, who consider it of second-rate compared to fresh fish,
showing a reluctance to purchase and consume it. In this regard, the term "defrosted" should
not appear on fishery and aquaculture products subjected to a preventive treatment for food
safety and health purposes (Regulation (EC) No. 404/2011). Beyond this, it would be
desirable that, at the retail level, the FBOs exposed an indication to clearly differentiate the
product defrosted from the remaining fish retained. At the same time, it would be also
desirable that not “Anisakis free” fish were distinguished by an indication, informing the
consumer that the product must be “consumed after cooking or after freezing”.

While the European legislation does not deal with the problem of consumer’s information,
in Italy, this issue has been considered many times (Decree of the President of the Regional
Council No. 282/49671, Ministerial Circular Letter 4379-P-17/02/2011, “Balduzzi” Decree
and Decree of July 17, 2013).

Some EU countries, such as Spain and France, have specified the technical parameters of
salting and pickling to kill the larvae of the parasite, thus excluding the preventive freezing of
the products. In Spain, the Scientific Committee of AESAN, following the entry into force of
the Royal Decree No. 1420/2006, asserted that freezing is not necessary for those fishery
products that reach a concentration of NaCl above 9% for at least six weeks (Comité
Científico de la Agencia Española de Seguridad Alimentaria y Nutrición, 2007), between 10
and 20% for four/five weeks or more than 20% for at least three weeks. With regard to the
salting, the French Food Safety Agency (Afssa), with the opinion No. 2007-SA-0379,
reported that in traditional preparations and for small quantities salinity levels of 20% result in
the inactivation of the parasite within 21 days, while concentrations of 15% require 28 days
(French Food Safety Agency, 2007). Afssa also reported that, according to some authors, fish
marinated with 10% acetic acid and 12% salt, maintained for 5 days at 4° C, are not
hazardous to health as well as marinated products with 12% salt and 6% of acetic acid for 13
days at 4° C. Finally, Afssa affirmed that the freezing treatment can also be replaced by either
irradiation or treatments with high pressures. Unfortunately, the irradiation procedure
requested to kill the parasite seems to induce changes in the organoleptic characteristic
(Farkas, 1998). In addition, in the EU the use of ionizing radiation for fishery products is not
approved by most of the Member States, including Italy (Directive 1999/3/EC and Notice No
2009/C 283/02). The organoleptic quality of the products is also compromised by too high
Twenty-five years ago, this kind of alternative approaches were already implemented by Germany (Ordinance of Federal Republic of Germany, 1988). In Italy an alternative technique was never defined and from the very beginning it was established the unconditional application of preventive treatment to all products to be consumed raw or almost raw.

3.2.7 Training of personnel. Considering the complexity related to the management of zoonotic parasites, the training of FBOs is fundamental for a thorough understanding of the issues associated to *Anisakis* spp.. However, this does not imply that the figure in charge for carrying out checking of goods ought to be the FBO, since the *Anisakis* risk needs scientific knowledge to be best managed. Therefore, it is essential that the FBOs are supported by specific professionals, such as veterinarians, who can assist them during controls. The "know how" of the veterinarian is also crucial to implement all the necessary preventive and corrective measures and to define the inspective outcomes. In this regard, the Local Veterinary Departments could consider the possibility that the responsible of large-scale retail or wholesale fish markets, where large quantities of fishery products are handled, could be supported in the management and control of parasites by a veterinarian, as the most suitable competent figure.

4. CONCLUSIONS

The Codex Alimentarius defines food hygiene as "*all conditions and measures necessary to ensure the safety and suitability of food at all stages of the food chain*". In this context, food safety, defined as “*the assurance that food will not cause harm to the consumer when it is prepared and/or eaten according to its intended use*”, represents the priority aspect. However, food has to be suitable for human consumption, in accordance to the purpose for which it is intended, beyond its safety. The presence of Anisakids larvae in fishery products is not only a public health issue, but it also determines a deterioration of the quality product making it repugnant to the consumer. Therefore, on the one hand it is necessary to avoid that products containing viable larvae can arrive to the consumer, on the other, it is also
appropriate to implement corrective measures aimed at reducing the perception of the  
problem by the consumers as recently occurred (Anonymus, 2013 and La Pira, 2013). In fact,  
even though the larvae had lost their pathogenic power, the products were found not to be  
suitable for sale, since repugnant. For this reason, and also in the view of current economic  
conditions and limited fish stocks, it would be desirable that alternatives were considered by  
the legislation in order to improve the management of the products affected by visible  
parasites. For example, the medium/large fish could be eviscerated in an equipped  
establishment, while those of small size could be exclusively marketed without viscera and  
the retailers could carry out a deferred evisceration at the time of retail.

Among the emerging critical issues there is also the need to implement harmonized  
policies during the inspections and controls: with regard to the sampling, the international  
laws do neither explain in detail how the visual inspection should be carried out nor specify a  
reference value to identify the "obviously contaminated" products. This uncertainty is largely  
due to the different perception/acceptance of the risk associated to Anisakidosis that  
characterizes each Countries, which is also reflected at the level of political bodies. Therefore,  
in Europe, there is an autonomy on measures to be taken, which are left to the Competent  
Authorities of each Member States. In Italy, beyond the inevitable local differences, the  
Competent Authorities have so far adopted a balanced approach between what is expected in  
terms of prevention by the European and Italian legislation and the need to protect, besides  
the public health, the production activities related to fishing and their economy. However,  
Anisakids do no longer involve a risk only for the lesions induced by the viable larvae, but  
also for the allergic reactions in sensitive subjects, which should be taken into consideration  
by establishing preventive measures, such as the reporting of Anisakids as allergenic in  
fishery products, as well as their inclusion in the list of all common allergens by the specific  
Finally, more than 20 years after the CL No. 10 of the Italian Ministry of Health, in which it was stated the importance of the veterinary inspector in the evaluation of an infected product, in a complex framework, such as that related to the Anisakis risk management, this professional figure is still essential, especially when a discriminating judgment is required, based on scientific knowledge and professional skill.

ACKNOWLEDGEMENTS

We thank Dr. Patrizia Buratti of ASL 14 Chioggia (Chioggia, Italy), Dr. Pietro Ceddia of ASL Roma H (ROMA, Italy), Dr. Francesco Giacomino of ASL TO3 (Pinerolo, Italy), Dr. Giuliana Giulini of Mare.A (Cattolica, Italy), Dr. Antonio Piccioni of ASL Teramo (Teramo, Italy) and Dr. Salvatore Madeddu of ASL 8 Cagliari (Cagliari, Italy) for providing us useful information and documents.
