We measure the time-dependent $CP$ asymmetry in the radiative-penguin decay $B^0 \to K_S^0 \pi^+ \pi^- \gamma$, using a sample of $471 \times 10^6 \Upsilon(4S) \to BB$ events recorded with the BABAR detector at the PEP-II $e^+ e^-$ storage ring at SLAC. Using events with $m_{K\pi \pi} < 1.8$ GeV$/c^2$, we measure the branching fractions of $B^+ \to K^+ \pi^- \pi^+ \gamma$ and $B^0 \to K^0 \pi^- \pi^+ \gamma$, the branching fractions of the kaonic resonances decaying to $K^+ \pi^- \pi^+$, as well as the overall branching fractions of the $B^+ \to \rho^0 K^+ \gamma$, $B^+ \to K^0 S \pi^+ \pi^- \gamma$ and $S$-wave $B^+ \to (K\pi)_0^+ \pi^+ \gamma$ components. For events from the $\rho$ mass band, we measure the $CP$-violating parameters $S_{K^0 S \pi^+ \pi^- \gamma} = 0.14 \pm 0.25 \pm 0.03$ and $C_{K^0 S \pi^+ \pi^- \gamma} = -0.39 \pm 0.20^{+0.03}_{-0.02}$, where the first uncertainties are statistical and the second are systematic. We extract from this measurement the time-dependent $CP$ asymmetry related to the $CP$ eigenstate $\rho^0 K^0$ and obtain $S_{K^0 S} = -0.18 \pm 0.32^{+0.06}_{-0.05}$, which provides information on the photon polarization in the underlying $b \to s\gamma$ transition.

DOI: 10.1103/PhysRevD.93.052013

I. INTRODUCTION

The $V$-$A$ structure of the Standard Model (SM) weak interaction implies that the circular polarization of the photon emitted in $b \to s\gamma$ transitions is predominantly left-handed, with contamination by oppositely polarized photons suppressed by a factor $m_f/mL$ [1,2]. Thus, $B^0$ mesons decay mostly to right-handed photons while decays of $B^0$ mesons produce mainly left-handed photons. Therefore, the mixing-induced $CP$ asymmetry in $B \to f\gamma$ decays, where $f$ is a $CP$ eigenstate, is expected to be small. This prediction may be altered by new-physics (NP) processes in which opposite helicity photons are involved. Especially, in some NP models [3–5], the right-handed component may be comparable in magnitude to the left-handed component, without affecting the SM prediction for the inclusive radiative decay rate. The present branching fraction measurement of $(B(B \to X_s\gamma)_{\exp} = (3.43 \pm 0.21 \pm 0.07) \times 10^{-4}$ [6]) agrees with the SM prediction of $(B(B \to X_s\gamma)_{\text{th}} = (3.36 \pm 0.23) \times 10^{-4}[7]$) calculated at next-to-next-to-leading order. Further information on right-handed photon could be obtained by measuring $CP$ asymmetries in different exclusive radiative decay modes. Furthermore, $B$ meson decays to $K\pi\pi\gamma$ can display an interesting hadronic structure, since several resonances decay to three-body $K\pi\pi$ final state (referred to as ”kaonic resonances” throughout the article). The decays of these resonances themselves exhibit a resonant structure, with contributions from $K^+\pi, K\rho$, and a $(K\pi)_0^+ \pi S$-wave component.

In the present analysis, we extract information about the $K\pi\pi$ resonant structure by means of an amplitude analysis of the $m_{K\pi\pi}$ and $m_{K\rho}$ spectra in $B^+ \to K^+ \pi^- \pi^+ \gamma$ decays. Assuming isospin symmetry, we use these results to extract
the mixing-induced CP parameters of the process $B^0 \rightarrow K^0_S\pi^\pm\pi^\mp\gamma$ from the time-dependent analysis of $B^+ \rightarrow K^0_S\pi^\pm\pi^\mp\gamma$ decays without an explicit amplitude analysis of this mode. Charge conjugation is implicit throughout the document.

The Belle Collaboration has previously reported a time-dependent CP asymmetry measurement of $B^0 \rightarrow K^0_S\pi^\pm\pi^\mp\gamma$ decays [8]. Similar measurements with $B^0 \rightarrow K^0_S\pi^\pm\pi^\mp\gamma$ decays have been reported by BABAR [9] and Belle [10]. No evidence for NP was found in these measurements. The observed CP asymmetry parameters are compatible with the SM predictions. LHCb has recently reported a nonzero value of the photon polarization in $B^+ \rightarrow K^-\pi^+\pi^-\gamma$ decays via the distribution of the angle of the photon with respect to the plane defined by the final state hadrons [11]. Studies of the processes $B^+ \rightarrow K^+\pi^-\pi^\mp\gamma$ and $B^0 \rightarrow K^0_S\pi^\pm\pi^\mp\gamma$ including measurements of the branching fractions have been performed by both BABAR [12] and Belle [13] using samples of $232 \times 10^6$ and $152 \times 10^6 BB$ pairs, respectively. The latter analysis also determined the branching fraction of the resonant decay $B^+ \rightarrow K_1(1270)^+\gamma$.

The article is organized as follows. In Sec. II we briefly describe the BABAR detector and the data set. In Sec. III we describe the analysis strategy. The amplitude analysis of $B^+ \rightarrow K^+\pi^-\pi^\mp\gamma$ decays and the time-dependent analysis of $B^0 \rightarrow K^0_S\pi^\pm\pi^\mp\gamma$ decays are described in Secs. IV and V, respectively. Finally, we summarize the results in Sec. VI.

II. THE BABAR DETECTOR AND DATA SET

The data used in this analysis were collected with the BABAR detector at the PEP-II asymmetric-energy $e^+e^-$ storage ring at SLAC. The sample consists of an integrated luminosity of 426.0 fb$^{-1}$ [14], corresponding to $(470.9 \pm 2.8) \times 10^6 BB$ pairs collected at the $\Upsilon(4S)$ resonance (“on resonance”) and 44.5 fb$^{-1}$ collected about 40 MeV below the $\Upsilon(4S)$ (“off resonance”). A detailed description of the BABAR detector is presented in Refs. [15,16]. The tracking system used for track and vertex reconstruction has two components: a silicon vertex tracker and a drift chamber, both operating within a 1.5 T magnetic field generated by a superconducting solenoidal magnet. A detector of internally reflected Čerenkov light (DIRC) is used for charged particle identification. The energies of photons and electrons are determined from the measured light produced in electromagnetic showers inside a CsI(Tl) crystal electromagnetic calorimeter (EMC). Muon candidates are identified with the use of the instrumented flux return of the solenoid.

III. ANALYSIS STRATEGY

The main goal of the present study is to perform a time-dependent analysis of $B^0 \rightarrow K^0_S\pi^\pm\pi^\mp\gamma$ decays to extract the decay and mixing-induced CP asymmetry parameters, $c_{K^0_p\rho}$ and $S_{K^0_p\rho}$, in the $B^0 \rightarrow K^0_S\rho^0\gamma$ mode. However, due to the large natural width of the $\rho(770)^0$, a non-negligible number of $B^0 \rightarrow K^+\pi^-(K^0_S\pi^\pm)\pi^\mp\gamma$ events, which do not contribute to $S_{K^0_p\rho}$, are expected to lie under the $\rho(770)^0$ resonance and modify $S_{K^0_p\rho}$. Using the formalism developed in Ref. [17], which assumes the SM, the “so-called” dilution factor $D_{K^0_p\rho}$ can be expressed as

$$D_{K^0_p\rho} \equiv \frac{S_{K^0_p\rho}}{S_{K^0_p\rho}} = \frac{\int |A_{R}\rho| K_{\rho}^0m_{\tau}^\pi^\mp\gamma}{\int |A_{R}\rho| K_{\rho}^0m_{\tau}^\pi^\mp\gamma} = \frac{\int |A_{R}\rho| K_{\rho}^0m_{\tau}^\pi^\mp\gamma}{\int |A_{R}\rho| K_{\rho}^0m_{\tau}^\pi^\mp\gamma} \frac{\int |A_{R}\rho| K_{\rho}^0m_{\tau}^\pi^\mp\gamma}{\int |A_{R}\rho| K_{\rho}^0m_{\tau}^\pi^\mp\gamma},$$

where $S_{K^0_p\rho}$ is the effective value of the mixing-induced CP asymmetry measured for the whole $B^0 \rightarrow K^0_S\pi^\pm\pi^\mp\gamma$ data set and $A_{R}\rho$ is the (complex) amplitude of the mode $RP$, where $R$ represents a hadronic resonance and $P$ a pseudoscalar particle. Here, $\Re(A)$ denotes the real part of the complex number $A$. We assume the final state $K^0_S\pi^\pm\pi^\mp$ to originate from a few resonant decay modes where $R$ corresponds to $\rho^0$, $K^{*+}$, $K^{*-}$, $(K\pi)^0_{\rho}$ or $(K\pi)^-_{\rho}$. Since a small number of events is expected in this sample, the extraction of the $A_{R}\rho$ amplitudes from the $B^0 \rightarrow K^0_S\pi^\pm\pi^\mp\gamma$ sample is not feasible. Instead, the amplitudes of the resonant modes are extracted from a fit to the $m_{K\pi}$ spectrum in the decay channel $B^+ \rightarrow K^+\pi^-\pi^+\gamma$, which has more signal events and is related to $B^0 \rightarrow K^0_S\pi^\pm\pi^\mp\gamma$ by isospin symmetry. Assuming that the resonant amplitudes are the same in both modes, the dilution factor is calculated from those of $B^+ \rightarrow K^+\pi^-\pi^+\gamma$. While the entire phase-space region is used to extract the amplitudes in the charged decay channel, the integration region over the plane of the $K^+\pi^-$ and $\pi^+\pi^-$ invariant masses in the calculation of $D_{K^0_p\rho}$ is optimized in order to maximize the sensitivity on $S_{K^0_p\rho}$. Note that the expression of $D_{K^0_p\rho}$ used in the present analysis slightly differs from the one used in the previous analysis performed by the Belle Collaboration [8].

Moreover, the decay to the $K^+\pi^-\pi^+\gamma$ final state proceeds in general through resonances with a three-body $K^+\pi^-\pi^+$ final state. Although the contributions of some of these states to the $B^+ \rightarrow K^+\pi^-\pi^+\gamma$ decay, such as $K_1(1270)$ or $K_2'(1430)$ have been measured, not all the contributions have been identified [18]. Since each of these resonances has different $K^+\pi$ and $K\rho$ mass spectra (see Sec. IV B 3), it is necessary to first determine the three-body resonance content of the $m_{K\pi}$ spectrum by fitting the charged $B^+ \rightarrow K^+\pi^-\pi^+\gamma$ sample.
Two types of Monte Carlo (MC) samples are used to characterize signal and background and to optimize the selection in both analyses of \( B^+ \to K^+ \pi^- \pi^+ \gamma \) and \( B^0 \to K^0_{\rm S} \pi^- \pi^- \gamma \). Generic \( B \bar{B} \) MC and MC samples for specific exclusive final states are used to study backgrounds from B-meson decays, whereas only MC samples for specific exclusive final states are used to study signal events. The size of the generic \( B \bar{B} \) MC sample approximately corresponds to 3 times that of the data sample.

### IV. AMPLITUDE ANALYSIS OF \( B^+ \to K^+ \pi^- \pi^+ \gamma \) DECAYS

In Sec. IV A, we describe the selection requirements used to obtain the signal candidates and to suppress backgrounds. In Sec. IV B 1, we describe the unbinned extended maximum-likelihood fit method used to extract the yield of \( B^+ \to K^+ \pi^- \pi^+ \gamma \) correctly reconstructed (CR) signal events from the data. Using information from this fit, the \( K^+ \pi^- \pi^+ \), \( K^+ \pi^- \), and \( \pi^+ \pi^- \) invariant-mass spectra (\( m_{K_{\pi\pi}} \), \( m_{K_L} \), and \( m_{\pi\pi} \)) for CR signal events are extracted by means of the \( \mathcal{P} \) plot technique [19]. In the second step, we perform a binned maximum-likelihood fit to the CR signal \( \mathcal{P} \) plot of \( m_{K_{\pi\pi}} \) to determine from data the branching fractions of the various kaonic resonances decaying to \( K^+ \pi^- \pi^+ \). Finally, we perform a binned maximum-likelihood fit to the CR signal \( \mathcal{P} \) plot of \( m_{K_L} \) to extract from data the amplitudes and the branching fractions of the two-body resonances decaying to \( K^+ \pi^- \) and \( \pi^+ \pi^- \). The use of a one-dimensional fit in this final step is purely pragmatic; with a larger sample size, a two-dimensional approach would have been possible. The \( m_{K_L} \) projection is used due to the narrower width of the \( K^+ (892) \) resonance compared with that of the \( \rho^0 (770) \). The \( m_{K_{\pi\pi}} \) and the \( m_{K_L} \) fit models are described in Secs. IV B 2 and IV B 3, respectively.

In Sec. IV C, we present the results of the three fits described above, and finally, we discuss systematic uncertainties on the results in Sec. IV D.

#### A. Event selection and backgrounds

We reconstruct \( B^+ \to K^+ \pi^- \pi^+ \gamma \) candidates from a high-energy photon, a pair of oppositely charged tracks consistent with pion hypotheses and one charged track consistent with a kaon hypothesis, based on information from the tracking system, from the EMC and from the DIRC. The center-of-mass energy of the photon is required to be between 1.5 and 3.5 GeV, as expected in a B radiative decay. The system formed by the final state particles is required to have a good-quality vertex.

A B-meson candidate is characterized kinematically by the energy-substituted mass \( m_{\text{ES}} \equiv \sqrt{(s/2 + p_\gamma \cdot p_B)^2/E_\gamma^2 - p_B^2} \) and energy difference \( \Delta E = E^\gamma - \sqrt{s}/2 \), where \( (E_\gamma, p_\gamma) \) and \( (E_B, p_B) \) are the four-vectors of the B candidate and of the initial electron-positron system, respectively, in the laboratory frame. The asterisk denotes the center-of-mass frame, and \( s \) is the square of the invariant mass of the electron-positron system. We require \( 5.200 < m_{\text{ES}} < 5.292 \text{ GeV}/c^2 \) and \( |\Delta E| < 0.200 \text{ GeV} \).

Since the \( \Upsilon (4S) \) is only just above the threshold for \( B \bar{B} \) production, the decay products from such events are approximately spherical in the center-of-mass frame, whereas \( e^+ e^- \to q\bar{q} \) \( (q = u, d, s, c) \) continuum background events have a dijettlike structure. To enhance discrimination between signal and the continuum background we use a Fisher discriminant [20] to combine six discriminating variables: the angle between the momentum of the B candidate and the beam (z) axis in the center-of-mass frame, the angles between the B thrust axis [21,22] and the \( z \) axis and between the B thrust axis and that of the rest of the event, the zeroth-order momentum-weighted Legendre polynomial \( L_0 \) and the second-to-zeroth-order Legendre polynomials ratio \( L_2/L_0 \) of the energy flow about the B thrust axis, and the second-to-zeroth-order Fox-Wolfram moments [23] ratio. The momentum-weighted Legendre polynomials are defined by \( L_0 = \sum_i |p_i| \) and \( L_2 = \sum_i |p_i|^{1/2} (3 \cos^2 \theta_i - 1) \), where \( \theta_i \) is the angle with respect to the B thrust axis of track or neutral cluster \( i \) and \( p_i \) is its momentum. The sums exclude the B candidate and all quantities are calculated in the \( \Upsilon (4S) \) frame. The Fisher discriminant is trained using off-resonance data for the continuum and a mixture of simulated exclusive decays for the signal. The final sample of candidates is selected with a requirement on the Fisher discriminant output value (\( F \)) that retains 90% of the signal and rejects 73% of the continuum background.

We use simulated events to study the background from B decays other than our signal (B background). In preliminary studies, a large number of channels were considered, of which only those with at least one event expected after selection are considered here. The main B backgrounds originate from \( b \to s \bar{q}q \) processes. B background decays are grouped into classes of modes with similar kinematic and topological properties.

In order to reduce backgrounds from photons coming from \( \pi^0 \) and \( \eta \) mesons, we construct \( \pi^0 \) and \( \eta \) likelihood ratios, \( \mathcal{L}_{R} \), for which the photon candidate \( \gamma_1 \) is associated with all other photons in the event, \( \gamma_2 \), such that

\[
\mathcal{L}_{R,\pi^0} = \frac{p(m_{\gamma_1/\gamma_2}, E_{\gamma_1}) |h^0\rangle}{p(m_{\gamma_1/\gamma_2}, E_{\gamma_1}) |K^+ \pi^- \pi^+ \gamma \rangle + p(m_{\gamma_1/\gamma_2}, E_{\gamma_1}) |h^0\rangle},
\]

where \( h^0 \) is either \( \pi^0 \) or \( \eta \), and \( p \) is a probability density function in terms of \( m_{\gamma_1/\gamma_2} \) and the energy of \( \gamma_2 \) in the laboratory frame, \( E_{\gamma_2} \). The value of \( \mathcal{L}_{R,\pi^0/\eta} \) corresponds to the probability for a photon candidate to originate from a \( \pi^0/\eta \) decay. We require \( \mathcal{L}_{R,\pi^0} < 0.860, \mathcal{L}_{R,\eta} < 0.957 \), resulting, if applied before any other selection cut, in a signal efficiency of \( \sim 93\% \) (95\%) and in background
TABLE I. Summary of B-background classes included in the fit model to \( B^+ \rightarrow K^+ \pi^- \pi^+ \gamma \) decays. If the yield is a free parameter in the fit, the listed values correspond to the fit result. Otherwise the expected value is given, which is computed from the branching fraction and selection efficiency. The terms “\( X_{\text{signal}} \)” designate all \( \mu \) decays but the \( K\pi \) final state. The functions used to parametrize the B-background probability density functions of \( m_{\text{ES}}, \Delta E \) and \( \mathcal{F} \) are also given. The notations “Exp”, “CB” and “\( \mathcal{G} \)” correspond to the exponential function, the Crystal Ball function [given in Eq. (6)] and the modified Gaussian function [given in Eq. (7)], respectively.

rejection factors of \( \sim 83\% (87\%) \) for continuum events and \( \sim 63\% (10\%) \) for B-background events.

The optimization of the selection criteria was done using the BumpHunter algorithm [24]. We optimized the \( S/\sqrt{S+B} \) figure of merit using several selection variables from which the kaon and pion particle identification levels, the \( \pi^0 \) and \( \eta \) likelihood ratios and the vertex \( \chi^2 \) of the system formed by the final state particles. In the optimization, we used CR signal events from simulation, off-resonance data for combinatorial background and generic \( BB \) simulated events (filtered to remove signal) for B backgrounds.

Table I summarizes the six mutually exclusive \( B \)-background classes that are considered in the present analysis.

B. The minimum-likelihood fit and extraction of the physical observables

1. The \( m_{\text{ES}}, \Delta E, \) and \( \mathcal{F} \) probability density functions (PDFs)

We perform an unbinned extended maximum-likelihood fit to extract the \( B^+ \rightarrow K^+ \pi^- \pi^+ \gamma \) event yield. We further obtain the signal \( m_{K\pi\pi}, m_{K\pi} \) and \( m_{\pi\pi} \) spectra, where the background is statistically subtracted using the \( \gamma \)Plot technique. Note that this technique may produce bins with negative entries. The fit is performed using the LAURA++ package [25]. The fit uses the variables \( m_{\text{ES}}, \Delta E, \) and the Fisher-discriminant output \( \mathcal{F}, \) to discriminate CR signal events from other event categories. The likelihood function \( \mathcal{L}_i \) for the event \( i \) is the sum

\[
\mathcal{L}_i = \sum_j N_j \mathcal{P}_j^i (m_{\text{ES}}, \Delta E, \mathcal{F}),
\]

where \( j \) stands for the event species (signal, continuum and the various \( B \) backgrounds) and \( N_j \) is the corresponding yield. The CR yield is a free parameter in the fit to the data, while the misreconstructed signal yield is fixed, defined as the product of the misreconstructed signal ratio obtained from simulation and the signal branching fraction taken from Ref. [18]. If no correlation is seen among the fitting variables, the PDF \( \mathcal{P}_j^i \) is the product of three individual PDFs:

\[
\mathcal{P}_j^i = \mathcal{P}_{m_{\text{ES}}}^j (m_{\text{ES}}) \mathcal{P}_{\Delta E}^j (\Delta E) \mathcal{P}_f^j (\mathcal{F}).
\]

Otherwise, the correlations are taken into account through multidimensional PDFs that depend on the correlated variables. The total likelihood is given by

\[
\mathcal{L} = \exp \left( -\sum_j N_j \right) \prod_i \mathcal{L}_i.
\]
The $\mu$ and $\sigma_l$ parameters are free in the fit to the data, while
the other parameters are fixed to values determined from simulations. Correlations between $m_{ES}$ and $\Delta E$ in CR signal are taken into account through a two-dimensional PDF. It is constructed as the product of a conditional PDF (CB for $m_{ES}$) by a marginal PDF ($\hat{G}$ for $\Delta E$). The dependences on $\Delta E$ of the CB parameters $\mu$ and $\sigma$ are parametrized by two second-order polynomials, while those of the parameters $\alpha$ and $n$ are parametrized by two first-order polynomials. The three parameters of both second-order polynomials are determined by the fit, while the parameters of the first-order polynomials are fixed in the fit to the values determined from simulations. The $F$ PDF of CR signal events is parametrized by a Gaussian, for which the mean and variance are left free in the fit to the data. No significant correlations were found between $F$ and either $m_{ES}$ or $\Delta E$.

The shape parameters of the PDFs of misreconstructed signal events are fixed to values determined from simulations. The $m_{ES}$ PDF is parametrized by the sum of an asymmetric Gaussian and of an ARGUS shape function [29], while the $\Delta E$ and $F$ PDFs are parametrized by a first-order polynomial and a Gaussian, respectively.

The $m_{ES}$, $\Delta E$ and $F$ PDFs for continuum events are parametrized by an ARGUS shape function, a second-order Chebychev polynomial and an exponential function, respectively, with parameters determined by the fit, except for the exponential shape parameter, which is fixed to the value determined from a fit to off-resonance data.

The $m_{ES}$, $\Delta E$ and $F$ PDFs for all the classes of $B$-background events are described by parametric functions, given in Table I, except for the $B^0 \to K\pi\gamma$ background $m_{ES}$ and $\Delta E$ PDFs, for which significant correlations are present. These are taken into account through a nonparametric two-dimensional PDF, defined as a histogram constructed from a mixture of simulated events. No significant correlations were found among the fit variables for the other species for the fit. The distributions of the combined $B^0\bar{B}^0$ and $B^+B^-$ generic $B$ backgrounds were studied using generic $B\bar{B}$ MC from which all other $B$-background class contributions were filtered out. The shape parameters of the $B$-background PDFs are fixed to values determined from simulated events. If the yield of a class is allowed to vary in the fit, the number of events listed in Table I corresponds to the fit results. For the other classes, the expected numbers of events are computed by multiplying the selection efficiencies estimated from simulations by the world average branching fractions [6,18], scaled to the data set luminosity. The yield of the $B^0 \to K\pi\gamma$ class, which has a clear signature in $m_{ES}$, and that of the generic $B$-background class are left free in the fit to the data. The remaining background yields are fixed.

### 2. The $m_{K\pi\pi}$ Spectrum

We model the $m_{K\pi\pi}$ distribution as a coherent sum of five resonances described by relativistic Breit-Wigner ($R_k$) line shapes [18], with widths that are taken to be constant. The total decay amplitude is then defined as

$$|A(m; c_k)|^2 = \sum_j \sum_k c_k R_k^j(m)^2,$$

with

$$R_k^j(m) = \frac{1}{(m_k^0)^2 - m^2 - i m_k^0 \Gamma_k^0},$$

and where $c_k = \alpha_k e^{i \phi_k}$ and $m = m_{K\pi\pi}$. In Eq. (8), the index $j$ runs over the different spin parities ($J^P$) and the index $k$ runs over the $K^+\pi^-\pi^+$ resonances of the same $J^P$. The coefficients $\alpha_k$ and $\phi_k$ are the magnitude and the phase of the complex coefficients, $c_k$, corresponding to a given resonance. Due to the fact that helicity angles are not explicitly taken into account in the fit model, it only has to account for interference between resonances with the same spin parity $J^P$. Table II details the resonances in the $m_{K\pi\pi}$ fit model. The $K_1(1270)$ magnitude is fixed to 1, and the $K_1(1270)$, $K^*(1680)$, and $K_2^*(1430)$ phases are fixed to 0. It has been checked that the choice of reference does not affect the results. The remaining parameters of the complex coefficients are left free in the fit: namely the $K_1(1400)$, $K^*(1410)$, $K^*(1680)$, and $K_2^*(1430)$ magnitudes as well as the two relative phases, that between the two $J^P = 1^+$ resonances and that between the two $J^P = 1^-$ resonances.

In addition to the complex coefficients, the widths of the two resonances, $K_1(1270)$ and $K^*(1680)$, are left free in the fit. In the case of the $K_1(1270)$, this is motivated by the fact that the width quoted in Ref. [18] might be underestimated according to the measurements reported in Ref. [30]. In the case of the $K^*(1680)$, the uncertainty on the width quoted in Ref. [18] is large. In total, eight parameters are kept free in the fit.

Note that we do not take phase-space effects into account here. However, distortions of line shapes of the $K^+\pi^-\pi^+$ resonances may occur from two sources: the available energy in the production process (i.e., $B \rightarrow K_{res} \gamma$), and a mass of intermediate-state particles close to threshold, as for instance in the case of $K_1(1270) \rightarrow K\rho(770)^0$. For each $K^+\pi^-\pi^+$ resonance, the first source of distortion is studied by comparing the invariant-mass distribution generated by EvtGen [31] to the $K_k$ mass used as an input to the generator. We see no significant distortion. For each resonance, the second source of distortion is estimated from the known properties of all decaying processes. Ideally, one should perform an iterative procedure in which the fit results converge to values compatible with the inputs.

The fit fractions $FF(k)$ for each resonance, as well as the interference fit fractions $FF(k,l)$ between the same $J^P$ resonances, are calculated as

$$FF(k) = \frac{|c_k|^2 \langle R_k R_k^* \rangle}{\sum_{\mu} \langle c_\mu c_\mu^* \rangle \langle R_\mu R_\mu^* \rangle},$$

$$FF(k,l) = \frac{2Re\{\langle c_k c_l \rangle \langle R_k R_l^* \rangle\}}{\sum_{\mu} \langle c_\mu c_\mu^* \rangle \langle R_\mu R_\mu^* \rangle},$$

where the terms $\langle R_\mu R_\mu^* \rangle$ are

$$\langle R_\mu R_\mu^* \rangle = \int R_\mu R_\mu^* dm.$$  \hspace{1cm} (12)

The sum of fit fractions is defined as the algebraic sum of all fit fractions. This quantity is not necessarily unity due to the possible presence of net constructive or destructive interference.

The branching fraction to the $K^+\pi^-\pi^+\gamma$ final state is determined from the fitted yield of the CR signal event category, $N_{CR}^{sig}$, the weighted CR signal efficiency $\langle e^+ \rangle$, and the number of charged $B$ events, $N_{B^+}$:

$$B(B^+ \rightarrow K^+\pi^-\pi^+\gamma) = \frac{N_{CR}^{sig}}{\langle e^+ \rangle \times N_{B^+}},$$

with

$$\langle e^+ \rangle = \sum_k \frac{FF(k)}{\sum_l FF(l)}.$$

Here, $k$ and $l$ run over the kaonic resonances, $e_k^+$ represents the efficiency without requirement on $m_{K_{ss}}$ for resonance $k$ listed in Table III and FF are the fit fractions extracted from a binned maximum-likelihood fit to the CR signal $\gamma$ Plot of $m_{K_{ss}}$ plotted in 80 bins. The term $N_{B^+}$ is obtained from the total number of $BB$ pairs in the full BABAR data set, $N_{BB}$, and the corresponding $\Upsilon(4S)$ branching fraction taken from Ref. [18]:

$$N_{B^+} = 2 \times N_{BB} \times B(\Upsilon(4S) \rightarrow B^+B^-) = (483.2 \pm 6.4) \times 10^6.$$  \hspace{1cm} (15)

The branching fraction of each kaonic resonance,

$$B(B^+ \rightarrow K_{res} \rightarrow K^+\pi^-\pi^-\gamma) = FF(k) \times \frac{N_{CR}^{sig}}{\langle e^+ \rangle \times N_{B^+}},$$

is computed using the corresponding fit fraction $FF(k)$ and efficiency accounting for the requirement on $m_{K_{ss}}$. $e_k^+$, listed in Table III.

### 3. The $m_{K_{ss}}$ spectrum

In a third step, we perform a binned maximum-likelihood fit to the efficiency-corrected CR signal $m_{K_{ss}}$ $\gamma$ Plot with 90 bins to extract amplitudes and branching fractions of the intermediate resonances decaying to $K^+\pi^-\pi^-$. The branching fractions of the intermediate state resonances are obtained using the averaged efficiency $\langle e^+ \rangle$ such that

$$B(B^+ \rightarrow Rh\gamma) = FF(R) \times \frac{N_{CR}^{sig}}{\langle e^+ \rangle N_{B^+}},$$

where $R$ denotes an intermediate state resonance and $h$ is either a kaon or a pion, and $FF(R)$ is the corresponding fit fraction. The resonance $R$ is decaying either to $K^+\pi^-$ when $h = \pi^+$ or to $\pi^+\pi^-$ when $h = K^+$. To correct for efficiency effects, we construct efficiency maps in the $m_{K_{ss}}$-$m_{ss}$ plane for each kaonic resonance in the fit model. For each exclusive decay, the efficiency map is determined from the phase-space decay of that resonance $[B^+ \rightarrow K_{res}(K^+\pi^-\pi^-)\gamma]$. The efficiency map of the combined sample shown in Fig. 1 is obtained by applying weights to the individual maps, which were extracted from the fit to the $m_{K_{ss}}$ spectrum. The $m_{K_{ss}}$ spectrum is corrected for
efficiency effects by dividing the \((m_{K\pi},m_{\pi\pi})\) distribution by the combined efficiency map and integrating over the \(m_{\pi\pi}\) dimension. The approach of projecting the \(m_{\pi\pi}-m_{K\pi}\) phase space of \(B^+ \to K^+ \pi^- \pi^+\gamma\) onto the \(m_{K\pi}\) axis was chosen since the sample size was too small for a two-dimensional fit. This is further complicated by the four-body nature of the decay: since the value of \(m_{K\pi}\) can vary from event to event, the kinematic boundaries for the \(m_{\pi\pi}-m_{K\pi}\) plane vary as well. We model the \(m_{K\pi}\) spectrum as the projection of two \(1^-\) \(P\)-wave and one \(0^+\) \(S\)-wave components. The two \(P\)-wave components, namely the \(K^*(892)^0\) and \(\rho(770)^0\) resonances, are described by relativistic Breit-Wigner (RBW) and Gounaris-Sakurai (GS) [32] line shapes, respectively. The \(0^+\) \(S\)-wave component of the \(K\pi\) spectrum, designated by \((K\pi)^0\), is modeled by the LASS parametrization [33], which consists of the \(K^0_{1}(1430)^0\) resonance together with an effective range nonresonant (NR) component.

Due to the relatively low mass of the \(K^+\pi^-\pi^+\) resonances, the line shapes of the two-body resonances are distorted; the phase space is noticeably different for events below and above the resonance pole mass. To account for this effect, we model the invariant-mass-dependent magnitude of each resonance \(R_j\) by: 
\[
\sqrt{H_{R_j}(m_{K\pi},m_{\pi\pi})},
\]
where \(H\) is a two-dimensional histogram. The \(K^*(892)^0\) and \(\rho(770)^0\) histograms are directly generated from the Monte Carlo event generator [31], while the LASS parametrized \(S\)-wave histogram is obtained by applying weights to the sample of phase-space-generated events, as described below. To take into account the interference between the components, invariant-mass-dependent phases \(\Phi_{R_j}(m)\) are required. We make the hypothesis that the phases can be directly taken from the analytical expression of the corresponding line shape:

![Graph](image.png)

**FIG. 1.** Combination of the efficiency maps for each kaonic resonance. The relative weights used for the combination are extracted from a fit to the \(m_{K\pi\pi}\) spectrum (Sec. IV C). Large fluctuations at high \(m_{K\pi}\) or \(m_{\pi\pi}\) are due to the small number of events.

The RBW parametrization used to determine the corresponding invariant-mass-dependent phase, \(\Phi_{K^*}(m_{K\pi})\), is defined as

\[
\Phi_{R_j}(m) = \arccos\left(\frac{\langle R_j(m) \rangle}{|R_j(m)|}\right)
\]

where \(m\) is the nominal mass of the resonance and \(\Gamma(m)\) is the mass-dependent width. In the general case of a spin-\(J\) resonance, the latter can be expressed as

\[
\Gamma(m) = \Gamma_0 \left(\frac{|q|}{|q_0|}\right)^{2J+1} \left(\frac{m_0}{m}\right) X_j^2(\frac{|q|}{|q_0|})
\]

The symbol \(\Gamma_0\) denotes the nominal width of the resonance. The values of \(m_0\) and \(\Gamma_0\) are listed in Table IV. The symbol \(q\) is the momentum of one of the resonance daughters, evaluated in the resonance rest frame. The modulus of \(q\) is a function of \(m\) and the resonance daughter masses \(m_a\) and \(m_b\), given by

\[
|q| = \frac{m}{2} \left(1 - \frac{(m_a + m_b)^2}{m^2}\right)^{1/2} \left(1 - \frac{(m_a - m_b)^2}{m^2}\right)^{1/2}
\]

The symbol \(|q|_0\) denotes the value of \(|q|\) when \(m = m_0\). The \(X_j(\frac{|q|}{|q_0|})\) function describes the Blatt-Weisskopf barrier factor [34] with a barrier radius of \(r\). Defining the quantity \(z = \frac{|q|}{|q_0|}\), the Blatt-Weisskopf barrier function for a spin-\(I\) resonance is given by

\[
X_{I=1}(z) = \sqrt{\frac{1 + z_0^2}{1 + z^2}}
\]

where \(z_0\) represents the value of \(z\) when \(m = m_0\).

For the \(\rho(770)^0\) we use the GS parametrization, which describes the \(P\)-wave scattering amplitude for a broad resonance decaying to two pions

\[
R_j(m) = \frac{1 + C \cdot \Gamma_0 / m_0}{(m_0^2 - m^2) + f(m) - i m_0 \Gamma(m)}
\]
TABLE IV. The three resonances included in the model used in the fit to the $m_{K\pi}$ spectrum and their line-shape parameters. The nominal mass and width of the resonance, $m_0$ and $\Gamma_0$, which are expressed in MeV/$c^2$, are taken from the references given in the table. The parameter $r$ for $\rho(770)^0$ and $K^*(892)^0$ is the Blatt-Weisskopf barrier radius, expressed in (GeV/$c$)$^{-1}$. The parameters $a$ and $r$ of the $(K\pi)^0$ are the scattering length and the effective range, respectively, both expressed in (GeV/$c$)$^{-1}$.

where

$$ f(m) = \frac{m_0^2}{q_0^2} q^2 (h(m) - h(m_0)) + (m_0^2 - m^2) \frac{dh}{dm^2} \bigg|_{m=m_0} $$

and $C$ is a constant that depends on the pion mass $m_\pi$ and the $\rho$ mass $m_0$ such that

$$ C = \frac{3}{\pi} \frac{m_\pi^2}{q_0^2} \log \left( \frac{m_0 + 2q_0}{2m_\pi} \right) + \frac{m_0}{2\pi q_0} - \frac{m_\pi^2 m_0}{\pi q_0}. $$

The function $h(m)$ is defined for $m > 2m_\pi$ such that

$$ h(m) = \frac{2}{\pi m} \log \left( \frac{m + 2q_0}{2m_\pi} \right). $$

with

$$ \frac{dh}{dm^2} \bigg|_{m=m_0} = h(m_0) \left( \frac{1}{8q_0^2} - \frac{1}{2m_0^2} \right) + \frac{1}{2\pi m_0^2}. $$

The $0^+$ component of the $K\pi$ spectrum is described by the LASS parametrization

$$ R_j(m) = \frac{m_{K\pi}}{q \cot \delta_B - i q} \left\{ \begin{array}{l} m_0 \Gamma_0 \frac{m_0}{q_0} \left( \frac{m^2}{m_{K\pi}^2} - \frac{m_{K\pi}^2}{m_0^2} \right) - im_0 \Gamma_0 \frac{m_0}{m_{K\pi} q_0}, \end{array} \right. $$

where $\cot \delta_B = \frac{1}{aq} + \frac{1}{2} r q$.

Table IV gives the parameters of the line shapes used to derive the invariant-mass-dependent phase of the components entering the fit model. The total amplitude for describing the $m_{K\pi}$ distribution can be written as

$$ |A(m_{K\pi}; c_j)|^2 = \int_{m_{K\pi}^{\min}}^{m_{K\pi}^{\max}} \left( \sum c_j \sqrt{H_{R_j}(m_{K\pi}, m_{\pi\pi})e^{i\Phi_j(m)}} \right)^2 dm_{\pi\pi} $$

with

$$ c_j = \alpha_j e^{i\phi_j} $$

and

$$ H_{R_j} = \int_{m_{K\pi}^{\min}}^{m_{K\pi}^{\max}} H_{R_j}(m_{K\pi}, m_{\pi\pi}) dm_{\pi\pi} $$

(31)

(see below for the expression of $I$):
The histograms used to describe the $m_{K\pi}$-dependent magnitudes of the $K^*(892)^0\pi$, $K\rho(770)^0$, and $(K\pi)^0\pi$ decays are depicted in Fig. 2. Those describing the $K^*(892)^0\pi$ and $K\rho(770)^0$ decay are both obtained from the projection onto the $m_{K\pi}$ axis of a two-dimensional histogram, constructed as the combination of the individual kaonic resonance contribution to the corresponding resonance [i.e. $K_{res}\rightarrow K^*(892)^0\pi$ or $K\rho(770)^0$]. The combination is performed using the relative weights between each $K^+\pi^-\pi^+$ resonance extracted from the $m_{K\pi}$ fit. The unusual shape of the $(K\pi)^0\pi$ distribution, obtained from the phase-space distribution of $B^-\rightarrow K_1(1270)^+\rightarrow K^+\pi^-\pi^+\gamma$ processes weighted by the LASS parametrization [see Eq. (28)], is due to phase-space effects. In the present analysis, the resonant part of the LASS is described by the $K_0^*(1430)$ scalar, which is very much suppressed. The dominant contribution comes from the nonresonant term that corresponds to the effective-range part. For each histogram used to build the total PDF, the number of bins is 450 and 100 in the $m_{K\pi}$ and $m_{\pi\pi}$ dimensions, respectively.

The term $I$ in Eq. (29) describes the interference among the components in the model. In the two-dimensional $m_{K\pi}$-$m_{\pi\pi}$ plane, the interference between the $(K\pi)^0\pi$ and the $(K\pi)$ $P$-wave components are proportional to a term containing the cosine of the helicity angle. Therefore, when integrating over the $m_{\pi\pi}$ dimension, this interference term vanishes. Since the fit is to be performed to an efficiency-corrected $m_{K\pi}$ distribution, we do not allow for $(K\pi)$ $S$-wave and $P$-wave interference in the model. The remaining source of interference comes from the $(K\pi)$ and $(\pi\pi)$ $P$-wave components, as well as from the $(K\pi)$ $S$-wave and the $(\pi\pi)$ $P$-wave components. The resulting expression for the interference term of the total PDF is given by Eq. (32), where $\Phi_R$ are the invariant-mass-dependent phases defined in Eq. (18).

We use the $K^*(892)^0$ coefficients as a reference, setting $\alpha_{K^*}=1$ and $\phi_{K^*}=0$. We checked that other choices do not affect the results. This leads to four free parameters in the fit: $\alpha_{\rho}, \phi_{\rho}, \alpha_{(K\pi)^0}$, and $\phi_{(K\pi)^0}$. The fit fractions $F_F(j)$ extracted for each component in the model are defined in the same way as in the $m_{K\pi}$ fit model [see Eqs. (10) and (11)].

C. Results

1. Event yield in $B^-\rightarrow K^+\pi^-\pi^+\gamma$ and $m_{K\pi\pi}$ spectrum

In the charged $B$-meson decay mode for $m_{K\pi\pi}<1.8 \text{ GeV}/c^2$, the unbinned maximum-likelihood fit of
$m_{\text{ES}}, \Delta E,$ and $\mathcal{F}$, as described in Sec. IV B 1, yields $2441 \pm 91_{-54}^{+41}$ correctly reconstructed signal $B^+ \to K^+\pi^-\pi^+\gamma$ events in data. This translates into a branching fraction of

$$B(B^+ \to K^+\pi^-\pi^+\gamma) = (24.5 \pm 0.9 \pm 1.2) \times 10^{-6}. \quad (33)$$

In both cases, the first uncertainty is statistical and the second is systematic. The latter is discussed in Sec. IV D 3. This result is in good agreement with the previous world average [18] and supersedes that of Ref. [12]. Figure 3 shows signal-enhanced distributions of the three discriminating variables in the fit: $m_{\text{ES}}, \Delta E,$ and $\mathcal{F}$. Using 331 generated pseudoexperiments with embedded signal events drawn from fully simulated MC samples, we checked that the parameters of interest exhibit no significant biases.

Figure 4 shows the extracted $m_{K_{\pi\pi}^+}$ distribution. The magnitudes and phases of the signal model components, as well as the widths of the $K_1(1270)$ and $K_1(1680)$ resonances, are extracted directly from a binned maximum-likelihood fit to the $P_{\text{plot}}$ distribution of $m_{K_{\pi\pi}^+}$. Using $m_{\text{ES}}, \Delta E,$ and $\mathcal{F}$, as described in Sec. IV B 1, yields $2441 \pm 91_{-54}^{+41}$ correctly reconstructed signal $B^+ \to K^+\pi^-\pi^+\gamma$ events in data. This translates into a branching fraction of

$$B(B^+ \to K^+\pi^-\pi^+\gamma) = (24.5 \pm 0.9 \pm 1.2) \times 10^{-6}. \quad (33)$$

In both cases, the first uncertainty is statistical and the second is systematic. The latter is discussed in Sec. IV D 3. This result is in good agreement with the previous world average [18] and supersedes that of Ref. [12]. Figure 3 shows signal-enhanced distributions of the three discriminating variables in the fit: $m_{\text{ES}}, \Delta E,$ and $\mathcal{F}$. Using 331 generated pseudoexperiments with embedded signal events drawn from fully simulated MC samples, we checked that the parameters of interest exhibit no significant biases.

Figure 4 shows the extracted $m_{K_{\pi\pi}^+}$ distribution. The magnitudes and phases of the signal model components, as well as the widths of the $K_1(1270)$ and $K_1(1680)$ resonances, are extracted directly from a binned maximum-likelihood fit to the $P_{\text{plot}}$ distribution of $m_{K_{\pi\pi}^+}$. Using

$$B(B^+ \to K^+\pi^-\pi^+\gamma) = (24.5 \pm 0.9 \pm 1.2) \times 10^{-6}. \quad (33)$$

In both cases, the first uncertainty is statistical and the second is systematic. The latter is discussed in Sec. IV D 3. This result is in good agreement with the previous world average [18] and supersedes that of Ref. [12]. Figure 3 shows signal-enhanced distributions of the three discriminating variables in the fit: $m_{\text{ES}}, \Delta E,$ and $\mathcal{F}$. Using 331 generated pseudoexperiments with embedded signal events drawn from fully simulated MC samples, we checked that the parameters of interest exhibit no significant biases.

Figure 4 shows the extracted $m_{K_{\pi\pi}^+}$ distribution. The magnitudes and phases of the signal model components, as well as the widths of the $K_1(1270)$ and $K_1(1680)$ resonances, are extracted directly from a binned maximum-likelihood fit to the $P_{\text{plot}}$ distribution of $m_{K_{\pi\pi}^+}$. Using
TABLE V. Results of the fit to the correctly reconstructed signal, \( \text{\itshape Plot} \) of \( m_{K\eta\pi} \). The first uncertainty is statistical and the second is systematic (see Sec. IV D 1). The uncertainties on the \( K_1(1270) \) and \( K^*(1680) \) widths are statistical only. Interferences for both \( J^P = 1^+ \) and \( 1^− \) resonances are destructive.

Eqs. (10) and (11), we further compute the FF corresponding to the different resonances and the interference among those with the same \( J^P \). The fitted parameters and FFs are listed in Table V. The statistical uncertainties on the magnitudes and phases, as well as on the widths of the \( K_1(1270) \) and \( K^*(1680) \) resonances, come directly from the fit. The central values of these widths are in good agreement with the corresponding world average values[18].

As the fit fractions are functions of the complex amplitudes \( c_k \), the statistical uncertainties on the FF are estimated in a different way. From the full fit result information (including correlations between fitted parameters) obtained using the nominal model, \( 10^5 \) sets of values of the resonance amplitudes \( c_k \) are randomly generated. We then compute the corresponding fit fractions for each set and obtain the FF(k) distributions. The \( \pm 1\sigma \) statistical uncertainties are taken as the values at \( \pm 34.1\% \) of the FF distribution integral along the FF value extracted from the nominal fit results. We also performed likelihood scans of the fitted parameters, as shown in Fig. 5, in order to check for the presence of multiple solutions. It appears that the fitted solution is unique. Each of these scans is obtained by fixing the corresponding parameter at several consecutive values and refitting the rest of the parameters. Each of the fits is repeated 30 times with random initial values of the varying parameters and always converge to the same likelihood solution.

Inserting the FF values listed in Table V into Eqs. (14) and (16), we obtain the weighted efficiency \( \langle \epsilon^+ \rangle = 0.2068^{+0.0010}_{-0.00017} \) and the branching fractions listed in Table VI. In the calculation of the branching fractions, we use both the fitted signal yield and the corresponding fit fraction. Since these two quantities come from measurements on the same data sample, we assume that the corresponding statistical uncertainties are 100% correlated when calculating the statistical uncertainty on each branching fraction. This is a conservative approach of determining the total statistical uncertainty.

2. The \( m_{K\eta\pi} \) spectrum

Figure 6 shows the efficiency-corrected \( m_{K\eta\pi} \), \( \text{\itshape Plot} \) distribution that is also extracted from the unbinned maximum-likelihood fit to \( m_{ES}, \Delta E, \) and \( \mathcal{F} \) and is corrected for efficiency effects (see Sec. IV B 3). The figure shows the contributions of the different two-body resonances, as extracted from the fit to the \( m_{K\eta\pi} \) spectrum itself. Table VII summarizes the relative magnitudes and phases of the different components of the signal model, measured directly from the fit to the \( m_{K\eta\pi} \) spectrum, as well as the corresponding fit fractions computed using Eqs. (10) and (11). The statistical uncertainties on the magnitudes and phases come directly from the fit while the statistical uncertainties on the fit fractions are estimated in the same way as those obtained in the fit to the \( m_{K\eta\pi} \) spectrum. As in the fit to the \( m_{K\eta\pi} \) spectrum, we perform likelihood scans of the fitted parameters, shown in Fig. 7, in order to check for multiple solutions. The fitted solution appears to be unique.

Table VIII summarizes the branching fractions via intermediate \( K^+\rho(770)^0 \), \( K^*(892)^0\pi^+ \) and \( (K\pi)^0\pi^+ \) decays that are obtained after inserting the two-body resonance fit fractions into Eq. (17). Since the \( (K\pi)^0 \) component is modeled by the LASS parametrization, which consists of a NR effective range term plus a relativistic Breit-Wigner term for the \( K_0^*(1430)^0 \) resonance, we report a separate branching fraction for the \( K_0^*(1430)^0 \) of \( \mathcal{B}(B^+ \to K_0^*(1430)^0\pi^+) = (1.44 \pm 0.19 \pm 0.26 \pm 0.14) \times 10^{-6} \) after correction for the \( \mathcal{B}(K_0^*(1430)^0 \to K\pi) \) [18] and the isospin factor of 2/3. The first uncertainty is
the second is systematic, and the third is due to the uncertainty on the secondary branching fraction. Since in this analysis the $K_{0}(1430)^0$ contribution is modeled exclusively in the decay process $B^+ \to K_1(1270)^+ \times (\to K_0^*(1430)^0 \pi^+)\gamma$, we extract a branching fraction of $B(K_1(1270)^+ \to K_0^*(1430)^0 \pi^+) = (3.34^{+0.62+0.64}_{-0.54-0.82}) \times 10^{-2}$, where the first uncertainty is statistical and the second is systematic. This result is in good agreement with the measurement performed by the Belle Collaboration in the analysis of $B \to J/\psi(\psi')K\pi$ decays [35], while it is significantly smaller than the value given in Ref. [18]. In the present analysis, the relative fraction between the resonant and NR part of the LASS is fixed while the overall $(K\pi)^0$ contribution is a free parameter in the fit. The NR contribution, described by the effective range part of the LASS parametrization, is found to be $(11.0^{+1.4+2.0}_{-1.5-2.5}) \times 10^{-6}$. As in the case of the three-body resonance branching fraction measurement, we assume a

FIG. 5. One-dimensional scans of $-2\Delta \ln \mathcal{L}$ as a function of magnitudes (top and middle) and phases (bottom). The horizontal dashed lines mark the one- and two-standard-deviation levels.
TABLE VI. Branching fractions of the different $K^+\pi^-\pi^+$ resonances extracted from the fit to the $m_{K\pi\pi}$ spectrum. The listed numbers are averaged over charge-conjugate states. They are obtained using the fit fraction of each component and the corresponding efficiency. To correct for the secondary branching fractions, we use the values from Ref. [18]. The first uncertainty is statistical, the second is systematic (see Sec. IV D 3), and the third, when present, is due to the uncertainties on the secondary branching fractions. When the symbol “n/a” is quoted, it indicates that the corresponding branching fraction was not previously reported.

100% correlation between the fitted signal yield and the fit fraction when calculating the statistical uncertainty on each branching fraction.

We compute the dilution factor defined in Eq. (1) by inserting the FFs extracted from the fit to the $m_{K\pi\pi}$ spectrum into the expressions listed in Appendix A, which show the relations between amplitudes and the FFs. To optimize the sensitivity to $S_{K\rho\rho}$, we impose in the dilution factor calculation the mass requirements $600 \leq m_{K\pi\pi} \leq 900 ~\text{MeV/c}^2$ and $m_{K_{\pi\pi}}^{\text{min}} \leq m_{K\pi\pi} \leq 845 ~\text{MeV/c}^2$ or $945 ~\text{MeV/c}^2 \leq m_{K\pi\pi} \leq m_{K_{\pi\pi}}^{\text{max}}$, where $m_{K_{\pi\pi}}^{\text{min}}$ and $m_{K_{\pi\pi}}^{\text{max}}$ denote the allowed phase-space boundaries in the $m_{K\pi\pi}$ dimension. The $m_{\pi\pi}$ mass requirement accounts for the distortion of the $\rho(770)^0$ line shape towards the low invariant mass region due to phase-space effects. Using the integration region defined above in the $m_{\pi\pi}$ and $m_{K\pi}$ dimensions, we obtain

$$\frac{1}{2}\left[\int |A_{\rho K_0^0}^j|^2 dm_{K\pi}\right] = 0.269 \pm 0.028,$$

$$\frac{1}{2}\left[\int |A_{K^+\pi^-\pi^+}\pi^-| dm_{K\pi}\right] = 0.078 \pm 0.002,$$

$$\frac{1}{2}\left[\int |A_{(K\pi)^0\pi^-}\pi^-| dm_{K\pi}\right] = 0.141^{+0.029}_{-0.027},$$

$$\frac{1}{2}\left[\int (A_{K_+^0\pi^-}\pi^-) dm_{K\pi}\right] = 0.090 \pm 0.006,$$

$$\frac{1}{2}\left[\int (A_{K_+^0\pi^-}\pi^-) dm_{K\pi}\right] = 0.149^{+0.052}_{-0.040},$$

where the uncertainties account for both statistical and systematic uncertainties, which are summed in quadrature. Inserting the above results into Eq. (1) yields

$$D_{K_+^0\pi^-} = -0.78^{+0.19}_{-0.17},$$

where the uncertainties are statistical and systematic uncertainties added in quadrature. The systematic uncertainties contribution are discussed in Sec. IV D.

D. Systematic uncertainties

Since the main purpose of the analysis of $B^+ \rightarrow K^+\pi^-\pi^+\gamma$ decays is to extract the dilution factor $D_{K_+^0\pi^-}$, we have studied the systematic effects that influence its value. The dilution factor uncertainties depend on uncertainties of the two-body amplitudes obtained from a fit to the $m_{K\pi\pi}$ spectrum (see Sec. IV D 2), themselves depending on the uncertainties of the kaonic-resonance amplitudes obtained from a fit to the $m_{K\pi\pi}$ spectrum (see Sec. IV D 1). Finally, in Sec. IV D 3, the systematic uncertainties
corresponding to the branching fractions measurements are described. For the combination of asymmetric systematic uncertainties, the method described in Ref. [36] was used.

1. Kaonic resonance amplitudes

Table IX gives the systematic uncertainties on the kaonic resonance amplitude parameters and Table X gives the systematic uncertainties on the corresponding fit fractions. The dominant sources of systematic uncertainty are the fixed parameters of the resonance line shapes in the $m_{K\pi}$ fit model. The large relative effect of fixed line-shape parameters on the magnitude and the fit fraction of the $K'_2(1430)$ are due to its small contribution.

To assign systematic uncertainties due to the fixed parameters in the fit to $m_{ES}$, $\Delta E$ and $\mathcal{F}$, we vary each of the fixed parameters within its uncertainty, based on a fit to the simulated event sample, and we repeat the fit. Since the $m_{ES}$-$\Delta E$ distribution of $B^0 \rightarrow K^{*0}(\rightarrow K\pi)\gamma + B^0 \rightarrow X_{sd}(\rightarrow K\pi)\gamma$ background events is described by a two-dimensional histogram, the fit is performed fluctuating the bin contents according to a Gaussian distribution centered

![Diagram](image)

FIG. 7. One-dimensional scans of $-2\Delta \ln L$ as a function of the magnitudes (left) and phases (right) of the $\rho(770)^0$ and $(K\pi)^0_0$ components. The horizontal dashed lines mark the one- and two-standard-deviation levels.
TABLE VIII. Branching fractions of the resonances decaying to $K\pi$ and $\pi\pi$ extracted from the fit to the $m_{K\pi}$ spectrum. The listed results are averaged over charge-conjugate states. They are obtained using the “fit fraction” of each component and the corresponding efficiency. $R$ denotes an intermediate resonant state and $h$ stands for a final state hadron: a charged pion or kaon. To correct for the secondary branching fractions, we used the values from Ref. [18] and $B(K'(892)^0 \to K^+\pi^-) = \frac{1}{2}$. The first uncertainty is statistical, the second is systematic (see Sec. IV D 3), and the third (when applicable) is due to the uncertainties on the secondary branching fractions. The last two rows of the table are obtained by separating the contributions from the resonant and the nonresonant part of the LASS parametrization. Integrating separately the resonant part, the nonresonant part, and the coherent sum we find that the nonresonant part accounts for 95.6%, the resonant contribution 7.92%, and the destructive interference $-3.52\%$. When the symbol “n/a” is quoted, it indicates that the corresponding branching fraction was not previously reported.

on the nominal bin content and with a width given by the corresponding statistical uncertainty. The procedure is repeated 50 times. The root mean square (rms) of the resulting distribution of fitted parameter values is taken as the systematic uncertainty. The fixed yields are varied according to the corresponding branching fraction uncertainties taken from Ref. [18]. For the categories describing a sum of modes, the fraction of each mode is varied according to the relative branching fraction uncertainties taken from Ref. [18]. The misreconstructed signal yield is varied according to the uncertainties due to the sample size of simulated events and the signal branching fraction uncertainty in Ref. [18]. The fixed yield of the generic $B$-background category, describing a sum of several small contributions from various $B$-background modes, is varied within the uncertainties due to the sample size of simulated events. For each new fit performed this way, we derive the corresponding $m_{K\pi}$, $sPlot$ distribution that we then fit using the nominal $m_{K\pi}$ model. Assuming no correlations among the fixed parameters, we combine each of the negative (positive) difference between the new fit value and nominal fit value of each free parameter and take the resulting values as negatively (positively) signed uncertainties.

To assign systematic uncertainties due to the choice of bin size in the fitted data set, we perform new fits using either 60 or 100 bins, instead of 80 in the nominal fit model.

To assign systematic uncertainties due to the fixed parameters of the line-shape resonances in the $m_{K\pi}$ fit model, we vary each of the eight fixed parameters according to its uncertainties, taken from Ref. [18], and redo the fit to the nominal CR signal $m_{K\pi}$, $sPlot$ distribution.

For the systematic uncertainties due to the fit model (i.e. the resonances describing the $m_{K\pi}$ spectrum), we vary the nominal model by adding other kaonic resonances at high masses to the fit model. We considered three additional resonances, the $K_0^*(1770)$, the $K_2^*(1780)$, and the $K_2^*(1820)$, whose parameters are given in Table XI. We add each of these resonances in turn to the model and reperform the fit to the CR signal $m_{K\pi}$, $sPlot$ distribution. We observe no variations on the parameters of the fit to the $m_{K\pi}$ spectrum when the $K_2^*(1820)$ is added to the

TABLE IX. Systematic uncertainties of the parameters of the kaonic resonance amplitudes extracted from a fit to the $m_{K\pi}$ spectrum. The symbol $\varnothing$ denotes a systematic uncertainty of zero, while 0.0 indicates that the corresponding systematic uncertainty is less than 0.05%.

resonance model. Using the method described in Ref. [36], we combine each of the negative (positive) difference between the new fit value and nominal fit value due to the presence of either the $K_2(1770)$ or the $K'_3(1780)$ in the resonance model.

If the yields of one or more event categories are fixed in the fit to an $\mathcal{P}$lot spectrum, a correction is necessary (see Ref. [19]) to extract the CR signal $\mathcal{P}$lot. This correction implies that the distributions of the variable of interest for the fixed categories are well known. The $m_{K\pi}$ distributions of the event categories with fixed yields cannot be considered to completely fulfill this criterion since they are taken from simulation. A detailed description of the evaluation of the systematic uncertainties due to the $\mathcal{P}$lot technique is given in Appendix B.

2. Two-body resonances

Table XII summarizes both the systematic uncertainties on the intermediate state resonance amplitude parameters and those on the corresponding fit fractions. The dominant sources of systematic uncertainty are the weights of the kaonic resonances extracted from the fit to the $m_{K\pi}$ spectrum. The relatively large systematic uncertainties on the $(K\pi)_0^0$ parameters and fit fraction are due to the low sensitivity to this component.

We account for two sources of systematic uncertainties from the number of bins: the first in the fitted $\mathcal{P}$lot (90 bins in the nominal fit model) and another in the two-dimensional histograms used to create the PDF (450 x 100 bins in the nominal fit model for $m_{K\pi} \times m_{\pi\pi}$). We estimate the effect of the bin size of the $\mathcal{P}$lot from fits performed with 75 and 105 bins, while the bin size of the PDF is fixed to its nominal value. We associate one systematic uncertainty to the bin size in $m_{K\pi}$ and another to that in $m_{\pi\pi}$. We estimate the effect of the bin sizes of the PDF, in the $m_{K\pi}(m_{\pi\pi})$ dimension, from fits performed with alternative PDFs with 270(50) and 630(150) bins in $m_{K\pi}(m_{\pi\pi})$, and the nominal number of bins in the other dimension. For each of these sources we take the lower and upper deviations from the nominal value of each FF as the corresponding uncertainty. We add the uncertainties coming from the bin size in $m_{K\pi}(m_{\pi\pi})$ in quadrature assuming no correlations between them.

To assign systematic uncertainties due to the fixed parameters in the fit to $m_{ES}$, $\Delta E$ and $F$, we use the procedure described in Sec. IV D 1. We derive a set of new $m_{K\pi}\mathcal{P}$lot distributions that we fit using the nominal model.

To account for systematic effects due to the fixed parameters of the resonances in the $m_{K\pi}$ fit model, we vary each of them according to the uncertainties given in Table IV. These parameters appear both in the line shapes used to generate the histograms of the resonances as well as in the corresponding analytical expressions of the phases. Therefore, for each parameter variation in a given line shape, we generate a new distribution of the corresponding resonance and use the same parameter value in the analytical phase expression. For each variation we perform a new fit to the nominal $m_{K\pi}\mathcal{P}$lot distribution. The largest effect is due to the line-shape parameters of the $K'_3(1430)$ part of the LASS parametrization, while effects coming from the $\rho(770)^0$ and $K^*(892)^0$ line-shape parameters are negligible.

To account for systematic effects due to the weights of kaonic resonances used to construct the PDF, we generate 10$^4$ sets of weights from the full $m_{K\pi}$ correlation matrix of fit fractions (taking into account the corresponding
TABLE XII. Systematic uncertainties of the parameters of the intermediate state resonance amplitudes and on the corresponding fit fractions extracted from a fit to the $m_{K\pi}$ spectrum. The symbol $\delta$ denotes a systematic uncertainty of zero, while 0.0 indicates that the corresponding systematic uncertainty is less than 0.05%. The term “Sum” represents the sum of all fit fractions without interference terms, which can deviate from unity. The quoted systematic uncertainties due to the number of bins in the fitted PDF correspond to the combined systematic uncertainties from the bins in $m_{K\pi}$ and $m_{K\pi}$, which were estimated separately as described in Sec. IV D 2.

3. Branching fractions

To assign systematic uncertainties on the yield for the CR signal category due to the fixed parameters in the fit to $m_{ES}$, $E$ and $F$, we use the same procedure as the one described in Sec. IV D 1. For each new fit, we obtain a new value of the CR signal event category yield. Using the method described in Ref. [36] and assuming no correlations among the fixed parameters, we combine each of the negative (positive) difference between the new fit value and nominal fit value of each free parameter and take the resulting values as negatively (positively) signed uncertainties.

We use 0.6% as the systematic uncertainty on $N_{B_{\bar{B}}}$, corresponding to the uncertainty on the official $B_{\bar{B}}$ count for the full $B_{\bar{B}}$ data set [37]. Similarly to Ref. [12], to account for possible differences between data and simulation in the tracking and particle identification efficiencies, we assign for each charged particle in the final state a systematic uncertainty of 0.24% and 1%, respectively.

The high energy photon selections applied in the present analysis are identical to those used in Ref. [12], except for the additional likelihood ratio vetoes applied against $\pi^0$ and $\eta$ decays. We adopt a 2% uncertainty for the requirement on the distance of the reconstructed photon energy cluster and the other energy clusters in the calorimeter and a 1% uncertainty due to the $\pi^0$ and $\eta$ vetoes, similarly to Ref. [12].

*aSince only upper and lower limits are reported in Ref. [18] for $B(K^*(1410) \to K\rho)$ and $B(K^*(1410) \to K^*(892)\pi)$, respectively, we take the $B(K^*(1410) \to K\rho)$ value as the reported upper limit for the calculation of $B(K_s^0(1400)^+ \to K^+ \pi^+ \pi^-)$, to which we assign a total uncertainty of 10%.*

The input branching fractions, as well as the corresponding uncertainties, used in the computation of the branching fractions, are taken from Ref. [18] and are summarized in Table XIII.

V. TIME-DEPENDENT ANALYSIS OF $B^0 \to K_S^0 \pi^- \pi^+ \gamma$ DECAYS

In Sec. VA, we describe the proper-time PDF used to extract the time-dependent $CP$ asymmetries. In Sec. VB, we describe the selection requirements used to obtain the signal candidates and to suppress backgrounds. In Sec. VC, we describe the fit method and the approach used to account for experimental effects. In Sec. VD, we present the results of the fit and finally, in Sec. VE, we discuss systematic uncertainties.

A. Proper-time PDF

The time-dependent $CP$ asymmetries are functions of the proper-time difference $\Delta t = t_{\text{rec}} - t_{\text{tag}}$ between a fully reconstructed $B^0 \to K_S^0 \rho^0 \gamma$ decay ($B^0_{\text{rec}}$) and the other $B$ meson decay in the event ($B^0_{\text{tag}}$), which is partially reconstructed. The time difference $\Delta t$ is obtained from the measured distance between the decay-vertex positions of $B^0_{\text{rec}}$ and $B^0_{\text{tag}}$. The distance is transformed to $\Delta t$ using the boost $\beta_\gamma = 0.56$ of the $e^+ e^-$ system.

The PDF for the decay rate is

$$p_{\text{sig}}(\Delta t, \sigma_{\Delta t}; q_{\text{tag}}, c) = \frac{e^{-(\Delta t)/\tau_{\rho^0}}}{4\tau_{\rho^0}} \left[ 1 + q_{\text{tag}} \frac{\Delta D_c}{2} + q_{\text{tag}} (D_c (S \sin(\Delta m_d \Delta t) - C \cos(\Delta m_d \Delta t))) \right] \otimes R_{\text{sig}}(\Delta t, \sigma_{\Delta t}),$$

where $\tau_{\rho^0}$ is the mean $B^0$ lifetime, $\Delta m_d$ is the mixing frequency [38], $S$ ($C$) is the magnitude for mixing-induced (direct) $CP$ violation, $q_{\text{tag}} = 1(-1)$ for $B^0_{\text{tag}} = B^0$ ($B^0_{\text{tag}} = B^0$), $(D)_c$ is the average tagging imperfection for determining the correct $B$ flavor using tagging category $c$ and $\Delta D_c$ is the difference between $D_c$ for $B^0$ and $B^0$ tags. We use a $B$-flavor tagging algorithm [39] that combines several signatures, such as particle type, charges, momenta, and decay angles of charged particle in the event to achieve optimal separation between the two $B$ flavors, producing six mutually exclusive tagging categories. We assign the untagged events into a seventh category. Although these events do not contribute to the measurement of the time-dependent $CP$ asymmetry, they do provide additional sensitivity for the measurement of direct $CP$ violation [40]. The exponential decay distribution modulated by oscillations due to mixing is convolved with the per-event $\Delta t$ resolution function $R_{\text{sig}}(\Delta t, \sigma_{\Delta t})$, which is parametrized by three Gaussian functions that depend on $\Delta t$ and its error $\sigma_{\Delta t}$. The parameters of the resolution function can vary for each tagging category.

B. Event selection and backgrounds

The reconstruction of $B^0 \to K_S^0 \pi^- \pi^+ \gamma$ candidates is identical to that of $B^+ \to K^+ \pi^- \pi^+ \gamma$ candidates except for replacing the $K^+$ with a $K_S^0$. The $K_S^0 \to \pi^- \pi^+$ candidate is required to have a mass within 11 MeV/$c^2$ of the nominal $K_S^0$ mass and a signed lifetime significance of at least five standard deviations. The latter requirement ensures that the decay vertices of the $B^0$ and the $K_S^0$ are well separated. In addition, combinatorial background is suppressed by requiring the cosine of the angle between the $K_S^0$ flight direction and the vector connecting the $B^0$ and the $K_S^0$ vertices to be greater than 0.995. Moreover, the $B^0$ candidates with $|\Delta t| > 20$ ps are rejected, and so are candidates for which the uncertainty on $\Delta t$ is larger than 2.5 ps. The additional selection criteria $0.6 < m_{\text{ee}} < 0.9$ GeV/$c^2$, $m_{\text{KS}} < 0.845$ GeV/$c^2$ or $m_{\text{KS}} > 0.945$ GeV/$c^2$ are applied for consistency with the corresponding requirements in the dilution factor calculation.

The set of variables used to build the Fisher discriminator in the analysis of $B^+ \to K^+ \pi^- \pi^+ \gamma$ decays (see Sec. VA) is also found to be optimal here. Therefore, we only update the coefficients in the linear combination to optimize the separation between signal and continuum background events. The requirement on the Fisher discriminator output value is optimized to minimize the statistical uncertainty on the $CP$ asymmetry parameters, $C_{K_S^0 \pi^+ \pi^- \gamma}$ and $S_{K_S^0 \pi^+ \pi^- \gamma}$. Furthermore, we again use the likelihood ratio, $L_{R}$, defined in Eq. (2), in order to reduce backgrounds from misreconstructed $\rho^0$ and $\eta$ mesons.

We use simulated events to study the $B$ backgrounds. Only the channels with at least one event expected after selection are considered. We observe that the main
TABLE XIV. Summary of $B$-background modes included in the fit model to $B^0 \rightarrow K^0_S \pi^+ \pi^- \gamma$ decays. If the yield is left free in the fit, the listed number of events corresponds to the fit results. Otherwise the expected number is given, which take into account the branching fractions (if applicable) and efficiencies. The functions used to parametrize the $B$-background PDFs are also given. The term “Exp.” corresponds to the exponential function. The PDFs for the $\Delta t$ distributions are discussed in Sec. V C 1. The terms “$X_{su(id)}(\rightarrow K\pi)$” denote all decays to $X_{su(id)}$ final states except for the $K\pi$ final state.

$B$ backgrounds originate from $b \rightarrow s\gamma$ processes. $B$-background decays are grouped into classes of modes with similar kinematic and topological properties. However, we distinguish $B$ backgrounds with different proper time distributions (see Sec. V C 1).

Table XIV summarizes the seven $B$-background classes that are used in the fit. If the yield of a class is allowed to vary in the fit, the quoted number of events corresponds to the fit results. For the other classes, the yields are estimated from efficiencies derived from the simulation together with the world average branching fractions [6,18]. When a $B$-background class contains a collection of many individual decay modes, as for the two generic $B$ backgrounds originatining from either $B^+$ or $B^0$ mesons, respectively, the expected numbers of selected events are estimated solely from Monte Carlo. The yield of the $B^+ \rightarrow K^0_S\pi^+\gamma$ class, which has a clear signature in $m_{ES}$, is free to vary in the fit. The remaining background yields are fixed.

C. The maximum-likelihood fit

We perform an unbinned extended maximum-likelihood fit to extract the $B^0 \rightarrow K^0_S\pi^+\pi^-\gamma$ event yields along with the time-dependent CP asymmetry parameters $S$ and $C$.

The PDFs in the fit depend on the variables: $m_{ES}$, $\Delta E$, $F$, $\Delta t$, and $\sigma_{\Delta t}$. The selected on-resonance data sample is assumed to consist of signal, continuum background, and backgrounds from $B$ decays. The likelihood function $L_i$ for event $i$ is the sum

$$L_i = \sum_j N_j \mathcal{P}_j(m_{ES}, \Delta E, F, \Delta t, \sigma_{\Delta t}; q_{tag}, c),$$

where $j$ stands for the event species (signal, continuum background, one for each $B$ background category) and $N_j$ is the corresponding yield.

The PDF for the event species $j$ evaluated for event $i$ is given by the product of individual PDFs:

$$\mathcal{P}_j(m_{ES}, \Delta E, F, \Delta t, \sigma_{\Delta t}; q_{tag}, c) = \mathcal{P}_j(m_{ES}) \mathcal{P}_{\Delta t}(\Delta t, \sigma_{\Delta t}; q_{tag}, c).$$

The total likelihood is given by

$$L = \exp \left( -\sum_j N_j \right) \prod_i \mathcal{L}_i.$$
of misreconstructed events to each tagging category and fix these fractions in the fit to the data.

For backgrounds from charged $B$ meson decays, the $\Delta t$ PDF is modeled as an exponential decay with an effective lifetime $\tau_j$:

$$
P_{B^0}(\Delta t, \sigma_{\Delta t}; q_{\text{tag}}, c) = \frac{e^{-|\Delta t|/\tau_j}}{4\tau_j} \times \left[ \frac{1 - q_{\text{tag}} A_j}{2} \right] \omega_c + \left[ \frac{1 + q_{\text{tag}} A_j}{2} \right] \left( 1 - \omega_c \right) \right. 
\left. \right) \otimes R_{\Delta t}^c(\Delta t, \sigma_{\Delta t}). 
\right) \right)
$$

where the index $j$ refers to the background event category, $A_j$ is the asymmetry accounting for possible differences between $B^0$ and $\bar{B}^0$ tags and $\omega_c$ is the mistag rate for tagging category $c$. For the background from neutral $B$ meson decays to flavor eigenstates (i.e. $B^0 \to K^\pm \pi^\mp \gamma$), a $\Delta t$ PDF similar to that for charged $B$ backgrounds is used, where mixing terms are added:

$$
P_{B^0}(\Delta t, \sigma_{\Delta t}; q_{\text{tag}}, c) = \frac{e^{-|\Delta t|/\tau_j}}{4\tau_j} \times \left[ \frac{1 - q_{\text{tag}} A_j}{2} \right] \omega_c + \left[ \frac{1 + q_{\text{tag}} A_j}{2} \right] \left( 1 - \omega_c \right) \right. 
\left. \right) \otimes R_{\Delta t}^c(\Delta t, \sigma_{\Delta t}). 
\right) \right)
$$

For backgrounds from neutral $B$ meson decays to $CP$ eigenstates, we account for possible $CP$ violation effects using a similar $\Delta t$ PDF as for signal with an effective lifetime

$$
P_{B^0}(\Delta t, \sigma_{\Delta t}; q_{\text{tag}}, c) = \frac{e^{-|\Delta t|/\tau_j}}{4\tau_j} \times \left[ \frac{1 - q_{\text{tag}} A_j}{2} \right] \omega_c + \left[ \frac{1 + q_{\text{tag}} A_j}{2} \right] \left( 1 - \omega_c \right) \right. 
\left. \right) \otimes R_{\Delta t}^c(\Delta t, \sigma_{\Delta t}). 
\right) \right)
$$

where $f_p$ corresponds to the fraction of prompt events and $\tau_{bg}$ corresponds to an effective lifetime. The resolution function, $R_{bg}$, is defined as the sum of a “core” and an “outlier” Gaussian function. The outlier Gaussian function has the bias fixed to $b_{out} = 0$, while the width and the bias of the core Gaussian function are scaled by the event-by-event uncertainty on $\Delta t$. The small contribution from $e^+ e^- \to c\bar{c}$ events is well described by the tails of the resolution function.

All the continuum background $\Delta t$ PDF parameters, except for $b_{out}$, are extracted from a fit to the off-resonance data sample. All $\langle D \rangle_c$ and $\Delta D_c$ values, tagging category fractions and asymmetries and all the $\sigma_{\Delta t}$ parameters are fixed in the fit to the data. All resolution function parameters are fixed in the fit except for that of the continuum background for which the mean and width of the core Gaussian function as well as the width and the fraction of the outlier Gaussian function are free parameters in the fit. Furthermore, the $S$ and $C$ parameters for signal are left free in the fit, while those for the $CP$-eigenstate neutral $B$ backgrounds are fixed to zero.

### 2. Description of the other variables

The $m_{ES}$ distribution of CR signal events is parametrized by the CB function defined in Eq. (6). The $\Delta E$ distribution of CR signal events is parametrized by a modified Gaussian defined in Eq. (7). The $\sigma_t$ and $\sigma_n$ parameters are free in the fit to the data, while the other parameters are fixed to values determined from simulated events. Correlations between $m_{ES}$ and $\Delta E$ in CR signal events are taken into account through a two-dimensional conditional PDF identical to the one used in the analysis of $B^+ \to K^+ \pi^- \pi^+ \gamma$. The dependences of the CB parameters $\mu$ and $\sigma$ on $\Delta E$ are parametrized by two second-order polynomials for which all the parameters are left free in the fit to the data, while the dependences of $\alpha$ and $n$ are parametrized by first- and second-order polynomials, respectively, for which all the parameters are fixed to values determined from fits performed to simulated events.

The $F$ distribution of CR signal events is parametrized by a Gaussian function for which the mean is left free in the fit to the data. No significant correlations were found between $F$ and either $m_{ES}$ or $\Delta E$.

All misreconstructed signal PDF shape parameters are fixed to values determined from simulated events. The $m_{ES}$ PDF of misreconstructed signal events is parametrized by the sum of a first-order Chebychev polynomial and an ARGUS shape function. The $\Delta E$ PDF is parametrized by a fourth-order polynomial and $F$ PDF is parametrized by the sum of a Gaussian function and an exponential.

The $m_{ES}$, $\Delta E$ and $F$ PDFs for continuum events are parametrized by an ARGUS shape function, a second-order Chebychev polynomial and an exponential function, respectively. The parameters of the second-order Chebychev polynomial are left free in the fit to the data. All
the other shape parameters are fixed to the values determined from a fit to the off-resonance data.

The $m_{ES}, \Delta E$ and $F$ PDFs for all the categories of B-background events, given in Table XIV, are described by parametric functions, except for the $B^+ \rightarrow K_s^0 \pi^+ \gamma B$ background $m_{ES}$ and $\Delta E$ PDFs, for which significant correlations are present. These correlations are taken into account through a nonparametric two-dimensional PDF, defined as a histogram constructed from a mixture of $B^+ \rightarrow K_s^0 \pi^+ (\rightarrow K_S^0 \pi^+ \gamma)$ and $B^+ \rightarrow X_{uo} (\rightarrow K_S^0 \pi^+) \gamma$ simulated events. All shape parameters of the B-background PDFs are fixed to values determined from simulation.

No significant correlations were found among the fit variables for the other event species in the fit.

3. Branching fraction determination

The branching fraction to the $K_S^0 \pi^+ \pi^- \gamma$ final state is determined from the fitted yield of the correctly reconstructed signal event category, $N_{CR}^{sig} = N_{sig} \times f^{CR}$, the weighted signal efficiency $\langle \epsilon^0 \rangle$, and the number of neutral $B$ events $N_{B^0}$:

$$B(B^0 \rightarrow K_S^0 \pi^+ \pi^- \gamma) = \frac{N_{CR}^{sig}}{\langle \epsilon^0 \rangle \times N_{B^0}},$$

(43)

where $\langle \epsilon^0 \rangle = 0.0553^{+0.0010}_{-0.0009}$ is obtained from Eq. (14) replacing the efficiencies $\epsilon^+_k$ by those of the neutral kaonic resonances listed in Table XV and, assuming isospin symmetry, using the FFs listed in Table V. The small value of $\langle \epsilon^0 \rangle$ compared to that of $\langle \epsilon^+ \rangle$ is due to the additional requirements on $m_{x\pi}$ and $m_{K_x}$ (see Sec. V B). The term $f^{CR} = 0.728 \pm 0.004$ is the fraction of correctly reconstructed signal events. The term $N_{B^0}$ is obtained from the total number of $BB$ pairs in the full BABAR data set, $N_{BB}$, and the corresponding $\Upsilon(4S)$ branching fraction taken from Ref. [18]:

TABLE XV. Efficiencies $\epsilon^0_k$ for correctly reconstructed signal candidates for each kaonic resonance from simulations without the applied requirement $m_{K_{x\pi}} < 1.8$ GeV/c$^2$. The efficiencies in the neutral mode are significantly smaller to the ones in the charged mode (see Table III) due to the additional requirements on $m_{x\pi}$ and $m_{K_x}$. The difference between the $\epsilon^0$ values is due to the difference in branching fractions of each kaonic resonance to the $K^+(892)^+ \pi^-$ and $K_S^0(770)^0$ decay modes.

D. Results

Requiring $m_{K_{x\pi}} \leq 1.8$ GeV/c$^2$, the unbinned maximum-likelihood fit to the data for the $B^0 \rightarrow K_S^0 \pi^+ \pi^- \gamma$ decay mode yields $N_{sig} = 243 \pm 24^{+21}_{-17}$ events and in turn a branching fraction of

$$B(B^0 \rightarrow K_S^0 \pi^+ \pi^- \gamma) = (20.5 \pm 2.0^{+2.6}_{-1.4}) \times 10^{-6},$$

(45)

where the first uncertainty is statistical and the second is systematic. This result is in good agreement with the previous world average [18]. The same convention holds for results in Eqs. (46)–(48). The systematic uncertainties are discussed in detail in Sec. V E 2. To check the presence of biases on the parameters of interest, 351 pseudoexperiments were generated with embedded signal events drawn from fully simulated MC samples and analyzed. No significant biases were found. Figure 8 shows signal-enhanced distributions of the four discriminating variables in the fit: $\Delta E$, $m_{ES}$, $F$, and $\Delta t$. The result of the fit to the data for the time-dependent CP violation parameters in signal events is

$$S_{K^0_{\pi^+\pi^-\gamma}} = 0.14 \pm 0.25 \pm 0.03,$$

(46)

$$C_{K_S^0\pi^+\pi^-\gamma} = -0.39 \pm 0.20^{+0.03}_{-0.02},$$

(47)

To obtain the value of $S_{K^0\pi^+\pi^-\gamma}$, we divide $S_{K^0_{\pi^+\pi^-\gamma}}$ by the dilution factor given in Eq. (34) and obtain

$$S_{K^0\pi^+\pi^-\gamma} = -0.18 \pm 0.32^{+0.06}_{-0.05}.$$

(48)

Table XVII shows the correlation matrix for the statistical uncertainty obtained from the fit to the data.

E. Systematic uncertainties

I. CP asymmetry parameters

In order to assign systematic uncertainties due to the fixed parameters in the fit to $m_{ES}, \Delta E, F$ and $\Delta t$, we vary each of the fixed parameters within its uncertainty, which are taken from different sources that are detailed below, and reperform the fit. The fixed shape parameters of $m_{ES}, \Delta E$ and $F$ PDFs are varied according to the uncertainties obtained in the fit to the simulated event samples from which they are extracted. Since the $m_{ES}\Delta E$ distribution of $B^+ \rightarrow K^+(\rightarrow K_S^0\pi^+ \gamma)+B^+ \rightarrow X_{uo}(\rightarrow K_S^0\pi^+ \gamma)$ background events is described by a two-dimensional histogram, we fluctuate the bin contents using the same procedure as described in Sec. IV D. The fixed yields are varied according to the corresponding branching
fraction uncertainties taken from Ref. [18]. For the categories describing a sum of modes, the fraction of each mode is varied according to the relative branching fraction uncertainties taken from Ref. [18]. The misreconstructed signal fractions are varied according to the uncertainties due to the sample size of the simulated events and the signal branching fraction uncertainties in Ref. [18]. The fixed yields of $B_0 \bar{B}_0$ and $B^+ B^-$ generic $B$ backgrounds, describing a sum of several small contributions from various $B$-background modes, are varied according to the uncertainties due to the sample size of the simulated events. The fixed parameters of the $\Delta t$ PDFs are varied according to the uncertainties that are either taken from other BABAR measurements or are extracted from simulated event distributions. Using the method described in Ref. [36] and assuming no correlations among the fixed parameters, we combine each of the negative (positive) difference between the new fit value and nominal fit value of each of the time-dependent $CP$-asymmetry parameters, and take the resulting values as negatively (positively) signed uncertainties.

The corresponding values are given in Table XVI. Note that these uncertainties are small compared to the statistical uncertainties.

2. Branching fraction

We take the same sources of systematic uncertainties as described in Sec. IV D 3 when applicable. A few sources, which are described below, differ from the analysis of $B^+ \rightarrow K^+ \pi^- \pi^+ \gamma$ decays.

From the procedure described in Sec. V E 1, and assuming no correlations among the fixed parameters, we combine each of the negative (positive) difference between the new fit value and nominal fit value of each of the total signal yield and take the resulting values as negatively (positively) signed uncertainties.

TABLE XVI. Systematic uncertainties on the time-dependent $CP$-asymmetry parameters resulting from the fixed parameters in the fit to $m_{ES}$, $\Delta E$, $F$ and $\Delta t$.

| $Yields$     | $K_S^0\pi^+\gamma$ | 100.0            | 4.7              | 1.4               | 6.6               | 0.1   | 1.1 | -0.2             | -0.7             | -0.9             | -0.9             | 0.1            | -0.3           | 0.3   | 2.3            | 1.1            | 1.1            | 0.3            | -0.6           |
Using Eq. (44), we compute the number of $B^0\bar{B}^0$ pairs using as input the branching fraction: $B(\Upsilon(4S) \rightarrow B^0\bar{B}^0) = 0.487 \pm 0.006$ taken from Ref. [18]. The branching fraction $B(K^0 \rightarrow K^0_s \rightarrow \pi^+\pi^-)$ is well measured [18] and we assign no systematic uncertainty due to this input. We apply a systematic uncertainty of 0.7% due to the $K^0_s$ reconstruction efficiency, as estimated using simulated events.

VI. SUMMARY

We have presented a measurement of the time-dependent $CP$ asymmetry in the radiative-penguin decay $B^0 \rightarrow K^0_s\pi^+\pi^-\gamma$, using a sample of 470.9×10^6 $\Upsilon(4S) \rightarrow B\bar{B}$ events recorded with the BABAR detector at the PEP-II $e^+e^-$ storage ring at SLAC. Using events with $m_{K}\pi < 1.8$ GeV/$c^2$, $0.6 < m_{\pi\pi} < 0.9$ GeV/$c^2$ and with $m_{K}\pi < 0.845$ GeV/$c^2$ or $m_{K}\pi > 0.945$ GeV/$c^2$, we obtain the $CP$-violating parameters $S_{K^0_s\pi^+\pi^-\gamma} = 0.14 \pm 0.25 \pm 0.03$ and $C_{K^0_s\pi^+\pi^-\gamma} = -0.39 \pm 0.20^{+0.03}_{-0.02}$, where the first uncertainties are statistical and the second are systematic. From this measurement, assuming isospin symmetry, we extract the time-dependent $CP$ asymmetry related to the $B^0 \rightarrow K^0_s\rho^0\gamma$ decay and obtain $S_{K^0_s\rho} = -0.18 \pm 0.32_{-0.05}^{+0.06}$. This measurement of time-dependent asymmetries in radiative $B$ decays is in agreement with previously published results [8–10] and is of equivalent precision. In this statistically-limited measurement, no deviation from the SM prediction is observed.

We have studied the decay $B^+ \rightarrow K^+\pi^-\pi^+\gamma$ to measure the intermediate resonant amplitudes of resonances decaying to $K\pi\pi$ through the intermediate states $\rho^0K^+$, $K^0\pi^+$ and $(K\pi)^0\pi^+$. Assuming isospin symmetry, these results are used to extract $S_{K\pi\pi\gamma}$ from $S_{K^0_s\pi^+\pi^-\gamma}$ in the neutral decay $B^0 \rightarrow K^0_s\rho^0\gamma$. In addition to the time-dependent $CP$ asymmetry, we gain information on the $K\pi\pi$ system which may be useful for other studies of the photon polarization. We have measured the branching fractions of the different $K_{res} \rightarrow K\pi\pi$ states and the overall branching fractions of the $\rho^0K^+$, $K^0\pi^+$ and $(K\pi)^0\pi^+$ components, listed in Tables VI and VIII, respectively.

ACKNOWLEDGMENTS

We thank E. Kou for help throughout the analysis, especially with the computation of the dilution factor, and A. Le Yaouanc for valuable discussions. We are grateful for the extraordinary contributions of our PEP-II colleagues in achieving the excellent luminosity and machine conditions that have made this work possible. The success of this project also relies critically on the expertise and dedication of the computing organizations that support BABAR. The collaborating institutions wish to thank SLAC for its support and the kind hospitality extended to them. This work is supported by the U.S. Department of Energy and National Science Foundation, the Natural Sciences and Engineering Research Council (Canada), the Commissariat à l’Énergie Atomique and Institut National de Physique Nucléaire et de Physique des Particules (France), the Bundesministerium für Bildung und Forschung and Deutsche Forschungsgemeinschaft (Germany), the Istituto Nazionale di Fisica Nucleare (Italy), the Foundation for Fundamental Research on Matter (Netherlands), the Research Council of Norway, the Ministry of Education and Science of the Russian Federation, Ministerio de Ciencia e Innovación (Spain), and the Science and Technology Facilities Council (United Kingdom). Individuals have received support from the Marie-Curie IEF program (European Union), the A. P. Sloan Foundation (USA) and the Binational Science Foundation (USA–Israel).

APPENDIX A: EXTRACTION OF THE DILUTION FACTOR

Using the hypothesis of isospin conservation, we assume that $B^0$ decays have the same amplitudes as $B^+$ decays. This allows us to use the results extracted from the fit to the $m_{K}\pi$ spectrum in $B^+ \rightarrow K^+\pi^+\pi^-\gamma$ decays from the measured amplitudes to obtain the dilution factor for the time-dependent analysis.

In the analysis of the $B^+$ decay, the amplitude of a resonance is modeled in $m_{12}$ as

$$F_{res} = c_{res}\sqrt{H_{res}(m_{12}, m_{23})}e^{i\Phi(m_{12})},$$  \hspace{1cm} (A1)

where $c_{res}$ is a complex constant and $H_{res}$ is a real distribution. $\sqrt{H_{res}(m_{12}, m_{23})}e^{i\Phi(m_{12})}$ being the line shape. Note that here $m_{12} = m_{K}\pi$ and $m_{23} = m_{\pi\pi}$. The total event rate [given here without the $(K\pi)$ $S$ wave for simplicity] is written as

$$|F|^2 = |F_\rho + F_{K^-}|^2.$$  \hspace{1cm} (A2)

In the analysis, we consider the total event rate from $B^+$ and $B^-$ in the $m_{K}\pi-m_{\pi\pi}$ plane. If the charge-sensitive amplitudes are denoted as $F_{res}^+$ and $F_{res}^-$, this implies the underlying assumption

$$|F_\rho + F_{K^-}|^2 = |F_{\rho}^+ + F_{K^+}^-|^2 + |F_{\rho}^- + F_{K^-}^+|^2,$$  \hspace{1cm} (A3)

or

$$|F_\rho|^2 + |F_{K^-}|^2 + 2Re(F_\rho F_{K^-}^*)$$
$$= |F_{\rho}^+|^2 + |F_{K^+}^-|^2 + |F_{\rho}^-|^2 + |F_{K^-}^+|^2$$
$$+ 2Re(F_\rho F_{K^+}^- + F_\rho^* F_{K^-}^+).$$  \hspace{1cm} (A4)

Assuming no direct $CP$ violation in the considered transition,
\[ F_\rho = \sqrt{2} F_\rho^+ = \sqrt{2} F_\rho^-, \quad (A5) \]
\[ F_{K'} = e^{i \delta_{\text{escat}}} \sqrt{2} F_{K'}^+ = \sqrt{2} F_{K'}^-, \quad (A6) \]

with \( \delta = \delta_{\text{escat}} = 0 \) or \( \pi \). Given that we measure a sizable interference between the \( \rho \) and the \( K' \) (see Table VII), we keep \( \delta_{\text{escat}} = 0 \). Indeed, \( \delta_{\text{escat}} = \pi \) would result in zero interference, as can be deduced from Eqs. (A4) and (A5).

Identical expressions are obtained for the \( (K\pi) \) S-wave terms. Using these conventions, the term \( |A_{\rho K_0^0}|^2 \) in Eq. (1) can be expressed as
\[ |A_{\rho K_0^0}|^2 = \frac{|F_\rho^+|^2 + |F_\rho^-|^2}{2} = \frac{|F_\rho|^2}{2}, \quad (A7) \]
whose contribution to the dilution factor is
\[ \frac{1}{2} \int |F_\rho|^2 = \frac{1}{2} |c_\rho|^2 \int_{m_{12}} \int_{m_{23}} |H_{\rho}(m_{12}, m_{23})|^2 dm_{12} dm_{23} = \frac{1}{2} FF_\rho, \quad (A8) \]
where \( FF_\rho \) is the measured fit fraction of the \( \rho \) resonance in the considered \( m_{K\pi} - m_{\pi\pi} \) domain.

The term \( |A_{K^+\pi^-}|^2 \) is expressed as
\[ \frac{|F_{K^+\pi^-}|^2 + |F_{K^-\pi^+}|^2}{2} = \frac{|F_{K^+}|^2}{2}, \quad (A9) \]
and its contribution to the dilution factor is
\[ \frac{1}{2} \int |F_{K^+}|^2 = \frac{1}{2} |c_{K^+}|^2 \int_{m_{12}} \int_{m_{23}} |H_{K^+}(m_{12}, m_{23})|^2 dm_{12} dm_{23} = \frac{1}{2} FF_{K^+}, \quad (A10) \]
where \( FF_{K^+} \) is the measured fit fraction of the \( K^+ \) resonance in the considered \( m_{K\pi} - m_{\pi\pi} \) domain.

Analogously, the term \( |A_{(K\pi)_0^0}|^2 \) is expressed as
\[ \frac{|F_{(K\pi)_0^0}|^2 + |F_{(K\pi)_0^-}|^2}{2} = \frac{|F_{(K\pi)_0^0}|^2}{2}, \quad (A11) \]
and its contribution to the dilution factor is
\[ \frac{1}{2} \int |F_{(K\pi)_0^0}|^2 = \frac{1}{2} |c_{(K\pi)_0^0}|^2 \int_{m_{12}} \int_{m_{23}} |H_{(K\pi)_0^0}(m_{12}, m_{23})|^2 dm_{12} dm_{23} \]
\[ = \frac{1}{2} FF_{(K\pi)_0^0}, \quad (A12) \]
where \( FF_{(K\pi)_0^0} \) is the measured fit fraction of the \( (K\pi) \) S-wave component in the considered \( m_{K\pi} - m_{\pi\pi} \) domain.

The term \( 2\Re(A_{\rho K_0^0}^* A_{(K\pi)_0^0}^- \pi^-) \) is expressed as
\[ 2\Re(F_{(K\pi)_0^0}^+ F_{K^-}^-) + 2\Re(F_{(K\pi)_0^0}^- F_{K^-}^+) \]
\[ = 2\Re \left( \frac{1}{\sqrt{2}} F_{\rho} F_{K^-} \right) \]
\[ = 2\Re \left( c_{\rho} c_{K^-} \sqrt{H_{\rho}(m_{12}, m_{23}) H_{K^-}(m_{12}, m_{23})} \right. \]
\[ \times e^{i(\phi_{\rho}(m_{12}) - \phi_{K^-}(m_{23}))}, \quad (A13) \]

With the notation \( c_{\text{escat}} = \alpha_{\text{escat}} e^{i \phi_{\text{escat}}} \), the contribution of the terms in Eq. (A13) to the dilution factor is given by Eq. (A15), where \( FF_{K'-\rho} \) is the measured fit fraction of the interference between the \( \rho \) and the \( K' \) resonances in the considered \( m_{K\pi} - m_{\pi\pi} \) domain, with the convention \( \alpha_{K'} = 1 \) and \( \phi_{K'} = 0 \). Analogously, the term \( 2\Re(A_{\rho K_0^0}^* A_{(K\pi)_0^0}^- \pi^-) \) is expressed as
\[ 2\Re(F_{\rho}^+ F_{(K\pi)_0^0}^-) + 2\Re(F_{\rho}^- F_{(K\pi)_0^0}^+) \]
\[ = 2\Re \left( \frac{1}{\sqrt{2}} F_{\rho}^+ F_{(K\pi)_0^0}^- \right) \]
\[ = 2\Re \left( c_{\rho} c_{(K\pi)_0^0}^* \sqrt{H_{\rho}(m_{12}, m_{23}) H_{(K\pi)_0^0}^-}(m_{12}, m_{23})} \right. \]
\[ \times e^{i(\phi_{(K\pi)_0^0}^*(m_{12}) - \phi_{(K\pi)_0^0}^-)(m_{23}))}, \quad (A14) \]

\[ \alpha_{\rho} \alpha_{K'} \int_{m_{12}} dm_{12} \int_{m_{23}} dm_{23} \sqrt{H_{\rho}(m_{12}, m_{23}) H_{K'}(m_{12}, m_{23})} \cos(\phi_{\rho} - \phi_{K'} + \phi_{\rho}(m_{23}) - \phi_{K'}(m_{12})) \]
\[ = \alpha_{\rho} \int_{m_{12}} dm_{12} \cos(\phi_{\rho} - \phi_{K'}(m_{12})) \int_{m_{23}} dm_{23} \sqrt{H_{\rho}(m_{12}, m_{23}) H_{K'}(m_{12}, m_{23})} \cos(\phi_{\rho}(m_{23})) \]
\[ - \int_{m_{12}} dm_{12} \sin(\phi_{\rho} - \phi_{K'}(m_{12})) \int_{m_{23}} dm_{23} \sqrt{H_{\rho}(m_{12}, m_{23}) H_{K'}(m_{12}, m_{23})} \sin(\phi_{\rho}(m_{23})) \]
\[ = \frac{1}{2} FF_{K'-\rho}, \quad (A15) \]
\[ \alpha_p \alpha_{\pi_{(\pi\pi)^0}} \int_{m_{12}} \int_{m_{23}} dm_{12} dm_{23} H_p(m_{12}, m_{23}) H_{\pi_{(\pi\pi)^0}}(m_{12}, m_{23}) \cos(\phi_p - \Phi_{\pi_{(\pi\pi)^0}}^p + \Phi_p(m_{23}) - \Phi_{\pi_{(\pi\pi)^0}}^p) \]

\[ = \alpha_p \int_{m_{12}} dm_{12} \cos(\phi_p - \Phi_{\pi_{(\pi\pi)^0}}^p(m_{12})) \int_{m_{23}} dm_{23} H_p(m_{12}, m_{23}) H_{\pi_{(\pi\pi)^0}}(m_{12}, m_{23}) \cos(\Phi_p(m_{23})) \]

\[ - \int_{m_{12}} dm_{12} \sin(\phi_p - \Phi_{\pi_{(\pi\pi)^0}}^p(m_{12})) \int_{m_{23}} dm_{23} H_p(m_{12}, m_{23}) H_{\pi_{(\pi\pi)^0}}(m_{12}, m_{23}) \sin(\Phi_p(m_{23})) \]

\[ = \frac{1}{2} \text{FF}_{\text{interf}}^{\pi_{(\pi\pi)^0} - p} \tag{A16} \]

whose contribution to the dilution factor is given by Eq. (A16), where \( \text{FF}_{\text{interf}}^{(K\pi)^0 - p} \) is the measured fit fraction of the interference between the \((K\pi)^0\) and the \(p\) resonances in the considered \(m_{K\pi} - m_{\pi\pi}\) domain.

**APPENDIX B: \( \mathcal{P} \text{LOT} \) TECHNIQUE**

The \( \mathcal{P} \text{LOT} \) technique corresponds to a background-subtracting method. It takes place in the context of an unbinned extended maximum-likelihood fit, making use of the discriminating variables denoted \(y\). The aim of \( \mathcal{P} \text{LOT} \) technique is to unfold the true distribution, \(M_n(x)\), of a variable \(x\), whose distributions are unknown for signal events. An estimate of the \(x\) distribution, denoted \(\bar{M}_n\), can be defined as the sum of the \(\bar{W}\) Weights in each bin, as described in Ref. [19]. If one or more event categories have their yields fixed in the maximum-likelihood fit, we need to apply a correction to reproduce a good estimate of the \(x\) distribution. This correction consists of adding to the \(\bar{M}_n\) histogram the normalized distributions of each fixed category scaled by the factor \(c_n = N_n - \sum_j V_{nj}\), where \(V\) is the covariance matrix resulting from the fit and \(N\) the expected yield of category \(n\). This procedure, which is used in the present analysis to extract the CR signal \(\mathcal{P} \text{LOT} \), implies that the \(x\) distributions of the fixed categories are well known. The \(m_{K\pi}\) distributions of the event categories with fixed yields cannot be considered to completely fulfill this criterion since they are taken from simulation. Therefore, we perform a new fit to \(m_{ES}, \Delta E\) and \(\mathcal{F}\), with all the previously fixed-yield categories merged to a single one to check for possible effects on the parameters of the fit to the \(m_{K\pi}\) and \(m_{\pi\pi}\) spectra. Since the shape of PDFs for the generic \(B\) background and that of the merged category are very similar, we add the former to the latter and consider them as a single “large background” category. This way, we can perform a fit with four event categories [i.e. CR signal, continuum, \(B^0 \to K^{*0} \to K\pi\gamma + B^0 \to X_{sl} \to (K\pi)^0\gamma\] and this new large background] where all the yields are left free in the fit. We observe good agreement between the fitted yields in the present and the nominal fit configurations. Thus, we extract the CR signal \(\mathcal{P} \text{LOT} \) distributions, where no corrections need to be applied since no event category yield is fixed in this configuration. We perform a fit to the new \(m_{K\pi} \) \(m_{\pi\pi}\) \(\mathcal{P} \text{LOT} \) distributions, using the nominal \(m_{K\pi} \) \(m_{\pi\pi}\) fit model, and take the deviation from the nominal value of each free parameter as the corresponding signed uncertainty.
